### To reduce the chance of by-effects

phine. These alkaloids are present in the same proportion as nature provides them in the poppy, but free from gums, resins, and inert materials. In such combination the therapeutic principles seem to have a natural balance that provides smoother opiate action, reducing the chance of by-effects so commonly encountered when morphine alone is used. That is why Pantopon has been adopted as a routine opiate by so many leading physicians in the various fields of medicine and surgery. When opiate medication is indicated, try 1/3 gr. of Pantopon 'Roche' instead of the usual 1/4 gr. of morphine. HOFFMANN-LA ROCHE, INC., ROCHE PARK, NUTLEY, NEW JERSEY.

### VI-MAGNA

### Lederle

I-MAGNA TABLETS Lederle provide a full of supplement for daily use by adults, adolo and older children. These thin, oval-shaped, swallowed tablets contain the fat-soluble vit A and D in a highly emulsified state. On sect Vi-Magna tablet exhibits a structure contain thousands of tiny droplets of fat-soluble material embedded in the tablet matrix. This provides tection from deterioration caused by contact air and encourages efficient absorption. Magna contains also the vitamin B confactors in concentrated form and vitamin C.

For supplementation of the diet with vil mins A, C, D and essential factors of t vitamin B complex. Each tablet contains:
Vitamin A (shark liver oil) 500 U.S.P. XII Units
Vitamin D (viosterol)
Ascorbic Acid (C)30 m
Thiamine HC1 (B <sub>1</sub> ) 3 m
Riboflavin (B <sub>2</sub> ) 2 ~
Niacinamide20
Calcium Pantothenate10
Pyridoxine HC1 (B <sub>6</sub> )0.2 mg
excipients, flavoring and artificial coloring.

#### IN NONCALCULOUS CHOLANGITIS

The first step in the treatment of acute cholangitis is to increase drainage into the duodenum. It is best accomplished by inducing a copious flow of thin liver bile. Free drainage tends to discourage ascent of infection, reduce subjective discomfort, and shorten the clinical course.

Decholin sodium offers a dependable means of increasing biliary flow and improving drainage. Injected intravenously, it creates an intense hydrocholeresis increasing bile flow as much as 200 per cent. The thin liver bile so produced washes before it undesirable debris and products of infection.

Oral treatment with Decholin tablets has a milder effect and is useful for prolonged medication. Decholin should not be employed in cholangitis due to calculi, and is contraindicated in complete obstruction of the common or hepatic bile duct.

#### LIPOLYSIN IN OBESITY FEMALE MALE

SAFELY DEPENDABLE

Lipolysin increases fat oxidation through stimulation of metabolic processes ... for safe, gentle and gradual reduction of excess poundage. A dependable pluriglandular preparation of high purity. No dinitrophenol.

Tablets and Capsules: bottles of 100. Ampuls: boxes of 12, 100. Physicians are invited to send for literature. Address Dept N.

CAVENDISH PHARMACEUTICAL CORP., 25 West Broadway, New York

### in a New...Cosmetic...Form

#### OF HIGH PHARMACEUTICAL ELEGANCE

Tarbonis\* has solved the problems which have so long shackled tar therapy, have so long kept it from being used as widely as its therapeutic value would justify.

It presents ALLTHETHERAPEUTIC PROPERTIES of crude tar, but in a form which immediately gains complete patient cooperation.

It is ODORLESS—all the offensive tar odor is removed, replaced by a pleasant discreet scent. It is NON-STAINING—it cannot be detected on the skin after application. It is NON-SOILING—it cannot stain or soil linen and clothing. It is GREASELESS—being a vanishing-type

cream it is in a highly cosmetic form, requiring no removal before reapplication. It is NON-IRRITANT.

The high therapeutic efficacy of TAR-BONIS has been demonstrated by almost a decade of clinical use. Its antipruritic, decongestant, remedial properties are of established value in every form of eczema, including infantile eczema, psoriasis, folliculitis, seborrheic dermatitis, industrial dermatoses (virtually regardless of cause), and in a number of other, especially pruritic, disorders in which tar is indicated.

THE TARBONIS COMPANY 1220 Huron Road, Cleveland 15, Ohio

\*Reg U S Pat. Off.

Tarbonis presents an especially processed Liquor Carbonis Detergens (5%), together with lanolin and menthol, in a special vanishing type cream. Available on prescription through all pharmacies, in 2½ or and 8 or jars. Physicians are invited to send for clinical test sample and the new comprehensive brochure on far medication.

# COCC... an improved form surface active saline mixture of AZOCHLORAMID, W&T

at no increase in cost

To the many physicians who rely upon AZOCHLORAMID preparations in the treatment of infected wounds, it is a pleasure to announce that the SALINE MIXTURE of AZOCHLORAMID is now available in SURFACE ACTIVE form at no advance in price.

The aqueous solution of SURFACE ACTIVE SALINE MIXTURE of AZOCHLORAMID contains AZOCHLORAMID 1:3300 and, in addition, sodium tetradecyl sulfate—a surface active (wetting) agent—1:1000. Its surface tension of only 30 dynes/cm. insures penetration of otherwise inaccessible areas of tissue effecting rapid contact between invading organisms and the bactericidal AZOCHLORAMID.\* Moreover, this solution effectively disperses pus and other organic debris from a wound suface. \*CHLOROAZODIN U.S.P.

Available in powder form in bottles to prepare 1 gallon or 25 gallons at hospital and prescription pharmacies.

Detailed literature and samples on request

The ORIGINAL ENTERIC COATED TABLET INE UKIGINAL ENIEKIO DALEN JABEL OF THEOBROMINE SODIUM ACETATE EFFECTIVE in Coronary Artery Disease and Edema\*

Clinical experience and carefully controlled studies in humans have definitely proven the value of Theobromine Sodium Acetate in treating certain Cardiovascular and Renal diseases, and the value of the enteric coating in permitting adequate dosage without causing gastric distress.

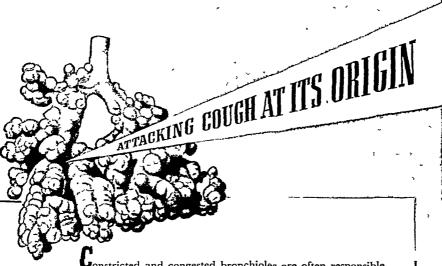

Supplied—in 7½ grains with and without Phenobarbital ½ grain; in 5 grains with Potassium Iodide 2 grains and Phenobarbital ¼ grain (cost approximately \$1.50 per bottle of 100 tablets); and in 334 grains with and without Phenobarbital 1/4 grain (cost approximately \$1.00 per bottle of 100). Capsules, not enteric coated, are available in the same potencies for supplementary medication.

\*Literature giving con-firming bibliography, and physicians sam-ples will be furnished on request

#### Worcester BREWER & COMPANY, INC.

Massachusetts

Pharmacoutical Chemists Since 1852

Constricted and congested bronchioles are often responsible for the factors that produce and prolong cough—causing serious discomfort and disturbed rest and sleep

#### NETHACOL

Brand of Expectorant and Bronchodilator

Nethacol contains the new sympathomimetic amine, Nethamine, which dilates the bronchioles without producing nervousness, palpitation, blood pressure elevation or other undesirable reactions. Nethacol also contains expectorant drugs which act to liquefy and remove congestion from the bronchioles and bronchi.

#### **FORMULA**

#### NETHACOL IS PLEASANT TASTING

Although sugar-free, Nethacol is unusually palatable. It provides an excellent vehicle for additional medication.

Recommended dosage of Nethacol is one or two teaspoonfuls, repeated as indicated. Children, proportionately less.

Nethacol is available at prescription pharmacies in pints and gallons.

Trade Marks "Nethacol" and "Nethamine" Reg. U.S Pat. On

## STREPTOCOCCUS INFECTIONS

Sulfadiazine Lederle

DRUG OF PREFERENCE

 ${
m T}_{
m HE}$  clinical effectiveness of this drug, together with the prolonged and easily maintained high blood levels, and the relative infrequency of serious toxic effects following its use, have made sulfadiazine the drug of preëminent value in the field of hemolytic streptococcal infections. Numerous publications have appeared upon the following indications-

Systemic Hemolytic Strepococcal Infections 1-16

Streptococcal and Miscellaneous Genito-Urinary Infections 1, 17

Hemolytic Streptococcal Infections of the Upper Respiratory Tract, Including Otitis Media, Tonsillitis and Mastoiditis 18-22 Prophylaxis of the Septic Complications of Scarlet Fever 1. 23. 24 Compound Fractures 6, 25-28

Nerve Suture in Military, or Civilian, Injuries 29

#### ADMINISTRATION

In serious hemolytic streptococcal infections, adults should receive an initial dose of 0.1 Gm./Kg. of body weight, to be followed by 1.0 to 1.5 Gm. every 4 hours day and night until the temperature has been normal for 5 to 7 days. In streptococcal pneumonia, adults should receive an initial dose of 4 Gm. by mouth followed by 1 Gm. every 4 to 6 hours until the temperature, pulse rate and respiration have been essentially normal for a period of 72 hours.

For further details of dosage, including that for children, and for parenteral dosage, see literature available from Lederle; or, New and Nonossicial Remedies, edition 1943.

During treatment with sulfadiazine, sulfathiazole or sulfapyridine, alkalis sufficient to maintain an alkaline urine should be administered unless contraindicated, and liquids should be given to produce a daily urinary output of between 1,000 and 1,500 cc. It is important to establish a full urinary output prior to the institution of parenteral therapy.

### HORLICK'S

#### IN THE WEANING PROGRAM

Rapidly and easily digested, more palatable than ordinary milk mixtures and withal well-balanced in nutritive values, Horlick's continues to play an important role in the weaning program.

A valuable nutritional habit is thereby inaugurated at the earliest possible opportunity, for with Horlick's the child receives:

#### EASILY DIGESTED PROTEIN—because

- (1) Prepared with water has zero curd tension
- (2) Prepared with milk has negligible curd tension

EASILY DIGESTED FAT—because Homogenized

EASILY DIGESTED CARBOHY-DRATE—because

Contains enzyme digested cereal starches

Horlick's Fortified is reinforced with additional amounts of vitamins A, B<sub>1</sub>, D and G.

Recommend
HORLICK'S

The Complete Malted Milk-Not Just a Malt Flavoring for Milk

## Physicians know from clinical experience

the reliability of

### Pil. Digitalis

(Davies, Rose)

They conform now,

as in the past,

with U.S.P requirements

Each pill is equivalent to I U.S.P. XII Digitalis Unit. "One United States Pharmacopœial Digitalis Unit represents the potency of 0.1 Gm. of the U.S.P. Digitalis Reference Standard."—U.S.P. XII.

Made from Powdered Digitalis Leaf, Pil. Digitalis (Davies, Rose) present all of the therapeutic principles obtainable from the drug.

Standardized according to Pharmacopœial requirements, they permit a uniform and accurate dosage.

These freshly prepared, standardized pills are put up in bottles of 35, forming a convenient package for the physician's prescription, obviating the necessity of rehandling.

Sample for clinical trial sent on request.

DAVIES, ROSE & COMPANY, Limited

BOSTON, MASSACHUSETTS, U.S.A.

### ARGYROL THE PHYSIOLOGIC ANTISEPTIC

There are important properties in addition to bacteriostasis which make ARGYROL the "Physiologic Antiseptic"—one which works in harmony with the normal defense functions of tissue, nerves, cilia, and circulatory system. Of first importance is the fact that ARGYROL is both antiseptic and decongestive. But there is an EXTRA FACTOR in mucous membrane antisepsis, in decongestion with ARGYROL. This is physiologic stimulation of tissue defense function. It is a combination of physico-chemical and bacteriostatic properties which go far beyond the usual concept of what an antiseptic should do. Write for further details, posological table and booklet of clinical application.

MADE ONLY BY THE A. C. BARNES COMPANY, NEW BRUNSWICK, NEW JERSEY

#### Sharp & Dohme

### 

for every indication

the newest ...

#### SULFAMERAZINE

Requires smaller or less frequent doses than sulfadiazine... Equally effective ... No more toxic.

Supplied in 0.25-Gm. and 0.5-Gm. tablets (bottles of 100, 500 and 1000), as Chemical Reagent (1-Gm. vial), and as Sodium Sulfamerazine Sterilized Powder for intravenous solutions (5-Gm. vial).

for enteric bacteriostasis . . .

SUCCINYLSULFATRIAZOLE

Highly effective against bacterial dysentery and as a prophylactic in intestinal surgery ... Less than 5 per cent absorbed

Supplied for oral use only as 0.5-Gm. tablets (bottles of 100, 500 and 1000) and as powder ( $\frac{1}{4}$ -lb. and 1-lb. packages).

Sulfadiazine . . . 0.5-Gm. tablets (bottles of 100 and 1000), Chemical Reagent (1-Gm. vial), Sodium Sulfadiazine Sterilized Powder (5-Gm. vial) for intravenous solutions.

Sulfathiazole . . . 0.25-Gm tablets (bottles of 50, 100, 500 and 1000). Sulfapyridine . . . 0 5-Gm tablets (bottles of 50, 100, 500 and 1000).

Sulfanilamide . . . 5-grain and 71/2-grain tablets (bottles of 25, 100, 500 and 1000).

SHARP & DOHMF Philadelphia 1, Pa.

### Procaine Hydrochloride and Epinephrine

The combination of the prompt and powerful local anesthetic action of procaine hydrochloride with epinephrine is very effective. With CHEPLIN'S PRO-CAINE HYDROCHLORIDE and

EPINEPHRINE the period of anesthesia is prolonged through retarded absorption of the anesthetic. It also causes blanching of the operative area, thus giving the surgeon a clear field.

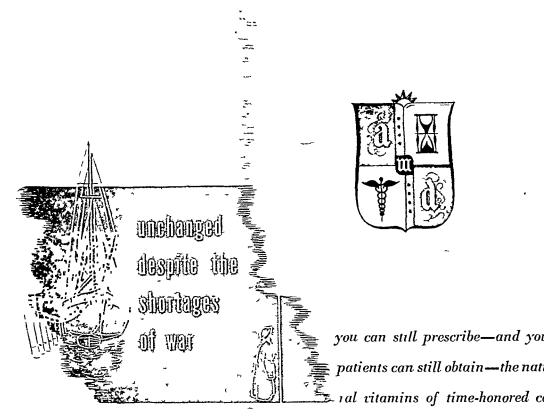

1% PROCAINE HYDROCHLORIDE and 1:25,000 EPINEPHRINE

is supplied for subcutaneous and intramuscular use in ampules and vials.

#### CHEPLIN BIOLOGICAL LABORATORIES, INC.

(Division of Bristol-Myers)
Syracuse, New York

liver oil itself, in the three pleasant dosage forms

### white's cod liver oil concentrate

··· drop dosage for infants; tablets for youngsters and adults; capsules for somewh larger dosage, or wherever capsular medication is preferred.

#### No Increase in Cost-to-Patient

Despite its advantages in potency, stability, palatability and convenience, the cost White's Cod Liver Oil Concentrate has always compared favorably with that of pla cod liver oil. Current shortages, however, have resulted in much higher prices for the plain oil, while the price to patient of White's Cod Liver Oil Concentrate has be maintained at its established economy level. Prophylactic antirachitic dosage for if fants STILL costs less than a penny a day. Council accepted: ethically promote White Laboratories, Inc., Pharmaceutical Manufacturers, Newark 7, N. J.

Sulmefin is available in 1-oz dropper packages and 1 pint bottles Pink inted solution

### Also Available SULMEFRIN OPHTHALMIC

A special formula for treatment of ophthalmic infections caused by sulfathiazole-sensitive organisms
Supplied in 1-oz. dropper bottles Yellow-tunted solu-

tion.

## SULMEFRIN\* gives relief from discomforts of winter colds

Shortens their course in some instances Relieves pressure pain in blocked sinuses

SULMEFRIN decreases congestion by the vasoconstrictor action of dl-desoxyephedrine hydrochloride, thus assisting the antibacterial action of sodium sulfathiazole. The vasoconstrictor is also believed to facilitate the sulfonamide in reaching the deeper layers of the nasal mucous membrane.

The mild alkalimity of Sulmefrin (pH approx. 90) is preferable according to Turnbull et al<sup>1</sup> for nasal medication because (1) the sulfonamide has the greatest bacterial action in the pH range from 8 to 10, and (2) because it allows ciliary action to continue for a long period of time.

Sulmefrin may be administered by spray, drops, or tamponage.

\* "Sulmefrin" (Reg. U. S. Pat. Off.) is a trade mark of E. R. Squibb & Sons J. A. M. A. 123-536, Oct. 30, 1943

#### Editorial

#### The New Year

The medical profession of the nation starts the new year with many grave problems still but partially solved. It may look back with pride and satisfaction upon the rapidity and thoroughness with which it has supplied the armed forces with competent medical personnel. While this task is not entirely finished, it is well on its way to accomplishment.

A good beginning has been made in the attempt to inform the public concerning the medical and hospital provisions of the proposed Wagner Bill. A great deal remains yet to be done in 1944 with respect to this proposed legislation. One of the contentions of medicine has been that the Surgeon General of the United States Public Health Service would be vested with too much power by the provisions of this Bill. In this connection it might be useful to have the views of the Surgeon General with respect to the Bill. The Journal of the Arkansas Medical Society for September, 1943, page 71, contains a letter dated July 19, 1943, addressed to Dr. R. B. Robbins, of Camden, Arkansas, in which the Surgeon General says as follows:

"I am in receipt of your letter of July 10 requesting my comment on Senate Bill 1161, and asking whether I favor it or not.

"There are a number of considerations which would prevent me from accepting this bill as it stands at present. There is, for example, the question as to whether a compulsory health (or sickness) insurance scheme is the best method for improving the health of the people. I believe other plans should be explored and the advantages and disadvantages of the several methods freely discussed.

"I feel also that everything possible should be

done to elicit constructive suggestions from outstanding leaders in the medical profession, and that the physicians now serving in the armed forces should have an opportunity to express themselves regarding plans which would greatly affect their professional careers...."

It might be well if this considered opinion of the man who would be the Czar of American Medicine if this bill were passed should be more widely publicized.

Many knotty questions related to the administration and acceptance of EMIC remain to be solved. In this state notable cooperation of the State Department of Health with the Medical Society of the State of New York has made possible a wide application of, if not complete agreement with, the plan of the Children's Bureau. It is to be hoped that the continuing efforts of the Department of Health and the State Medical Society may, in the coming year, resolve many of the remaining difficulties.

The continued progress of the armed forces is encouraging. Success, however, from a military point of view, carries with it an expectation of great casualty lists and therefore more numerous problems to be solved by the medical profession. The success in saving of life by means of improved medical care carries with it the probability of the survival of a greater number of those who will need continuing medical and other assistance as they return to civilian life. The national, state, and county societies are already giving this matter consideration, especially with respect to the problem of the placement and reinstatement of members of

### In Nutritional Deficiencies

The rationing of important iron-giving foods deserve serious consideration as a possible cause for existing and potential iron deficiencies for many.

The authorities manifest growing concern over the ever increasing cases of anemias. Such conditions indicate that never before has it been so important to look at the blood! Anemias of nutritional origin are effectively and economically corrected by the administration of specially prepared iron (easily assimilated ferrous sulphate—plain or with liver concentrate) incorporated in ...

center largely about domestic issues, medicine is certain to be involved, for its services touch in one way or another nearly every aspect of human life and activity. It would be well to consider that the year 1944 will be merely one in a long succession of years gone by and to come. It will pass as others have done before, adding its quota to human misery, and contributing its sand grain to the pitifully small pile representing human gains.

To all our members, and particularly those in the armed forces. Happy New Year and speedy victory.

#### The Annual Meeting

This year the Annual Meeting of the Medical Society of the State of New York will be held May 8-11 at the Hotel Pennsylvania, New York City. To many of our members it will very possibly seem strange that we meet this year in a different portion of the city than heretofore, for this will be the first time that the annual meeting will have been held at the Hotel Pennsylvania. This is merely one of the numerous changes necessitated by the war, but we hope that the many advances in the art and science of medicine, hastened in great measure by that same war, may prove a lodestone which will attract our membership to the fullest ex-

The scientific and other exhibits are pouring m, and in this connection it may be well to emphasize that January 20, 1944, will be the last day for listing the scientific exhibiters, according to the announcement of the chairman of the committee on the scientific exhibits of the convention committee. It will be of great assistance to the committee if prospective exhibitors will file their applications well in advance of the closing

It will be well for all our members now to mark off on their calendars the dates May

Many aspects of medical practice and of the relationship of the profession to allied professions, hospitals, agencies of government, are changing so rapidly that it is becoming more and more imperative for all those who can to attend the Annual Meeting. Everyone owes it to his community to keep abreast of these changes. More and more the public wants to know what is happening in medicine. It is only right that it should be able to obtain accurate and upto-date information concerning these changes from the physicians in each locality. This imposes an additional obligation on every physician to keep himself informed of present and prospective plans. Many physicians are members of their local service clubs, their church organizations, and of many civic bodies. There is thus afforded an enormous opportunity for the doctors of the country and of New York State in particular to discuss these matters with lay people and to inform the public of the attitude of physicians with respect to proposals for change in the practice of medicine. It is the will of the people which prevails through their representatives in the various state legislatures and in the Congress of the United It is important for physicians to bear this in mind, and to be able to act in an advisory capacity in their several localities to all those who may wish advice and information concerning proposed changes.

While the Medical Society of the State of New York, through its various publications and other channels, endeavors to keep its membership as fully informed as possible, the mechanism by which information is channeled from the Council of the Society through the columns of the Journal and the publications of the Bureau of Public Relations necessarily slows down somewhat the speed with which it can be brought before the membership of the Society. Added to this is the delay arising from the pressure of practice and other affairs which still further delay the doctor in his acquisition of this published information. He simply does not have the time to read it.

But at the Annual Meeting he is presented with the opportunity of catching up with the latest information on all these topics, to fill in the gaps which may have occurred since the previous Annual Meeting. This year, probably more than any previous year, it will be necessary for all physicians to be fully the medical profession. This year, however, will bring home the shortage of physicians and nurses available for civilian medical service. Mild epidemics are already beginning to appear as fatigue and strain take their toll of human reserves of physical and nervous energy.

Advances in chemotherapy have shortened the period of treatment and consequently the cost of many illnesses—pneumonia and meningitis, for example. Surely this will be reflected in less time lost from work, and a reduction in the over-all cost of medical care, including hospitalization and necessary nursing service.

Tuberculosis has not as yet shown the expected increase usual in wartime-for what reasons seems not yet to be clear, but the fact appears to be incontrovertible. is possible that the long education of the public through the efforts of the medical profession, the health departments, and the voluntary agencies is beginning to bear In this connection, the better understanding of the principles and practice of nutrition should not be overlooked. Knowledge of the vitamins, recently acquired and accepted by the public, better preservation and conservation of foods, and betterbalanced diets are undoubtedly playing a major role in the betterment of the public health.

Medicine must serve the needs of the nation perhaps more quickly and intimately than any other profession. It is therefore highly necessary that it remain, as heretofore, extremely fluid in its structure and function. It must be able to some extent to forecast the public need and to concentrate its now considerably diminished forces to meet actual and pressing emergencies. It would appear to be an inopportune time to introduce the inevitable rigidity of government control, but, on the other hand, a most opportune time to expand the mechanisms of the organized profession for keeping in touch with the trend of public thinking. Medical education is largely out of the sphere of control of the profession, owing to circumstances of the war. An increasing number of medical graduates will have had very little contact with or appreciation of public opinion or the problems of domestic medicine. This fact, though not of immediate importance, is bound in the end to have a considerable influence, commencing probably in this year 1944, when increasing numbers of them will return to their communities.

The question of prepaid medical and hospital insurance remains to a great extent unsolved. It cannot wait forever. Many states of the Union have no prepayment plan at all. The number of these is twentysix; and the District of Columbia is also in this group.

The rest of the states either have plans in full operation or regional plans in operation on an experimental basis.

This record is not good enough. Some experience with the mechanism of prepaid insurance is now available and it can no longer be said that the actual experience is entirely lacking. Granted that this experience is not complete, there is nevertheless available sufficient to warrant a more general experimentation with this type of coverage. We hope that the year 1944 will see a more or less unified plan in general operation throughout New York State. We have held out prepaid insurance plans as the antidote for the poison of socialized medicine. If that is so, that antidote must be available everywhere and to anyone who needs it. Organized medicine will have to recognize the fact that this type of insurance must be It must be sold to the public, and it is our belief that it must be sold to the public by those who know how to do it. If the doctors can do it, well and good; but of this we have doubts. If it is proper for the shoemaker to stick to his last it is equally proper for physicians to stick to their doc-They are not trained as salesmen of insurance. If organized medicine will recognize this fact and adjust its thinking to the utilization of some sales agency for this type of insurance which knows how to sell it. things will move faster. We believe that this is the time, if ever, to do some straight thinking on this subject. If we are to oppose effectively a national plan for socialized medicine, we must oppose it with an alternative plan on an operating basis, sufficiently widespread to support our contention.

An election year in the course of a war must necessarily add stresses not usually encountered. Since these stresses must

#### TREATMENT OF ARTERIAL EMBOLISM OF THE EXTREMITIES— A THREE-PHASE DIVISION

FREDERICK S. WETHERELL, M.D., Syracuse

A RTERIAL embolism of the extremities is a A catastrophe which, almost without exception, is first seen by the family physician. Quick recognition and rapid institution of therapy are, therefore, practically always so-called medical problems: the practitioner becomes the first hope of salvation for the threatened limb. If it were impossible to save the part, a physician would be justified in carrying out the old line of treatment: opiates, heat to the extremity, and watchful waiting. With increasing success in the treatment of arterial embolism. however. this hopeless attitude must be revised.

Sudden pain in the foot or leg, or in the hand or arm, accompanied by pallor and paralysis, the "three P's," plus a pulse deficit and other signs of auricular fibrillation, clinch the diagnosis. bolism is simulated by the final, complete closure of sclerotic vessels, but the story is different. In the latter there have likely been several previous indications of impaired circulation-e.g., attacks of intermittent claudication. Embolic block is sudden, out of a clear sky, and dramatic. We see an unforgettable picture: marble-like whiteness, light purplish-blue mottling, and coldness of the skin: inability to move the foot or toes, or in case of the upper extremity, the fingers or hand; absence of pulsation of the artery supplying the part, loss of the sense of touch, and excruciating pain, barely controlled by morphine.

Inasmuch as this is a discussion of treatment, further remarks on diagnosis, history of the disease, and historical aspects will not be covered. The latter are fully discussed by Pratt in a recent article.1

It is only within the past decade that reports of successful embolectomies have appeared in increasing number in the American literature use of anticoagulants, notably heparin, is without question the reason for the more frequent successes. The danger of postoperative clotting, at the site of the arterial incision and suture, has been greatly diminished by the use of this drug.

It is now generally recognized that the arteriolar spasm of the collateral vessels, which accompanies the lodgment of an embolus, diminishes or even completely blocks the collateral circulation which, if unaffected, would in many instances furnish temporary nourishment, later increasing

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 6, 1943. From the Department of Surgery, Syracuse University

College of Medicine.

to replace the supply formerly furnished by the closed main vessel.

Personal experience and observation suggest that treatment may be divided into three phases.

#### Treatment

First Phase.—Papaverine, a vasodilator drug, will in some instances be sufficient in itself to establish collateral circulation. Once the diagnosis is established, the patient should immediately be given a dose of 1/2 to 2 grains (0.30 to 0.120) Gm.) if given intramuscularly, to be repeated in two or three hours: one-half this dose if given intravenously. The surgeon who has been called will be confronted with the necessity of locating the exact site of the embolus. Lack of arterial pulsation distal to the embolus and oscillometric readings aid in this determination. If an oscillometer is not available, a sphygmomanometer may be used. The diagnosis is not always simple. Lack of acumen led me on one occasion to lay hare the brachial artery above the elbow: the popliteal instead of the femoral artery, in another case. In each instance, however, it was thought by several observers that pulsation could be felt above the site of incision shortly before operation was begun. The adage that "It is probably higher than you think" held true in both instances. A knowledge of the incidence of site of embolic block is valuable. It is approximately as follows:

	Percentage
Bifurcation of aorta	4.5
Iliac	17.0
Femoral	55.0
Popliteal	11.0
Brachial	12.0

If an improvement in circulation is noted following the administration of papaverine, as evidenced by increasing warmth of the affected part and return of the sense of touch and motion, even to a small degree, an attitude of watchful waiting may be justified. It is essential that the patient be in a hospital during this period of observation and that the improvement be progressive. At this point the thermocouple becomes an aid in estimating increasing local temperature; its value is, however, distinctly secondary to that of the oscillometer.

Second Phase: Sympathetic Nerve Block .-The possibility that a good result will ensue from this time on is usually so doubtful that a proinformed on the advances being made in practical plans for prepayment insurance, in plans for furthering group medicine, and further steps being taken to check the type

of legislation contained in the medical and hospital provisions of the Wagner Bill

So mark your calendars for May 8-11, 1944, Hotel Pennsylvania, New York City.

# Mortality in Children with Rheumatic Fever

"Children with theumatic fever," says the Statistical Bulletin of the Metropolitan Life Insurance Company, "are subject to a very high mortality during the acute phase of the disease, but once this stage is passed the death tate falls sharply."

In view of the current interest in the treatment of rheumatic fever, these statistical observations should be of interest. The study which brought out these facts was done on 2,817 policyholders of the Company under the age of 20, who received nursing care between the years 1936 and 1938 by the Company's visiting nuise service during an acute attack of the disease, and have been followed up each year since then.

Says the Bulletin:

"In this period, with an average duration of observation of nearly five years for the group as a whole, 257, or one out of every 11, have died. This mortality is about fifteen times as high as would be expected in a group of young people of like sex and age distribution. The death rate among the boys has been about one-fifth greater than among the girls.

"The individual histories available for this study generally did not indicate whether the child suffered a first or a recurrent attack—an important factor in the prognosis. That the cases studied were of more than average severity may be inferred from their age distributions as well as from the fact they were ill enough to require nursing care. "Children who were definitely reported to have

"Children who were definitely reported to have heart involvement during the attack for which they were nursed have had a much higher mortality than the other cases. In this group, containing less than one-fourth of the cases in the study, there occurred 152, or nearly 60 per cent, of all the deaths. Since there is some degree of heart involvement in practically every attack of rheumatic fever, whether or not reported, it may be concluded that the cases in which a heart condition was actually reported represent the most severe in the study.

"Mortality was especially high in the first year following the acute attack for which the children were nursed. Among those with reported heart involvement during the attack, nearly one-fifth died in the first year. The actual death rate was 184 per 1,000 per annum, as compared with 23 per 1,000 in the second year, and an average of 16 in the subsequent period of observation. In contrast, a death rate of little more than one per 1,000 has prevailed among children of these ages in the general experience of the Company. Among the other cases nursed (those without reported heart involvement), the first-year death rate was 18 per 1,000, or only one-tenth that of the group with cardiac involvement. In the second year of observation, the death rate in these other cases was 11 per 1,000, and in the remaining period it averaged 7 per 1,000. Even this rate is about five times the usual mortality.

"Heart disease was reported as the cause of 80 per cent of the deaths among the children in the study."

## Correspondence

12 East 87th Street New York December 14, 1943

Editor, New York Stafe Journal of Medicine Dear Doctor

Doctor Lowsley's paper in the current [December 1, 1943] issue of the State Journal on plastic induration of the penis is most interesting. However, he does not describe the further potential changes which may take place in these areas of induration. Not uncommonly, calcification of these areas follows, so that a veritable "bone" is formed in the septum, usually on its dorsal aspect. These calcified areas do not contain true bone structure (Haversian systems). A true os penis is,

however, regularly found in some of the lower mammals. Very rarely in the human subject, this bone is fractured during cortus, as I reported in 1914 in the Annals of Surgery. There is no record of such an occurrence in the lower animals.

This form of pathology is very commonly a late manifestation of syphilis in combination frequently with a local chronic form of irritative trauma, as from the wearing of a corset. In the more flaced noncalcified form of induration, there is a frequent instory of a preceding gonorrhea in which the inflammatory process spreads outside of the urethra into the penile septa

Very truly yours, A. O. Wilensky, M.D.

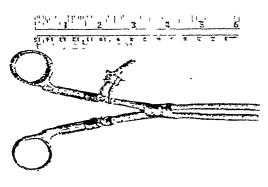

Fig. 2

through the suture line if a tendency to clotting is noted. If heparin is not administered preoperatively, the surgeon may find that a supposedly dry wound becomes a well of tiny arterial "oozers," when the heparin becomes fully effective postoperatively: a troublesome hematoma forms. This occurred in two cases: one in the arm, in which heparin was not given until the operation was completed; and another in which the popliteal space was opened in error and then closed before the femoral embolectomy was done. Here it would have been better to have left the first wound open until circulation had been re-established, thus making it possible to attain meticulous hemostasis, each tiniest bleeder being clamped and tied. Wound healing was perfect in the cases in which heparinization was instituted before the embolectomy was done, and the wound then made surgically dry before closure.

Although it is to be presumed that the preoperative sympathetic nerve block has ablated all vasoconstrictor impulses, and that the effect will be lasting if alcohol has been used in addition to procaine, it is still possible that the artery may constrict following the operative manipulations of incision and repair. This occurred in the case of a femoral embolism. the completion of the arterial suture, pulsation was forceful down to the incision but the artery below the suture line was quiet. A few drops of I per cent procaine were injected into the wall of the artery proximal to the repair, just under the external coat, using a small hypodermic needle. The circulation was immediately reestablished. To assure paralysis of the vasoconstrictor impulse for a short time postoperatively it may be well to thus inject a small quantity of procaine routinely.

5 The use of dicoumarin, \* replacing the hepa-

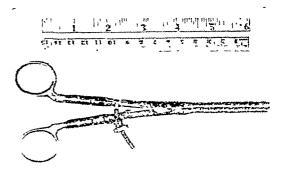

Fig. 3

rin effect after the first twenty-four to forty-eight hours, will considerably lower the cost of treatment. It has been completely effective in maintaining a low prothrombin percentage. In one instance (Case 4) there was vaginal bleeding which required blood and plasma transfusions before it was controlled. The drug is given orally; administration is begun coincidentally with the heparin infusion.

#### Case Histories

The following case histories will be epitomized to the extent of reporting mainly the treatment, with such collateral observations as seem important.

#### Embolectomy

Case 1.—L. C., a man aged 63, a truck driver, was admitted to St. Joseph Hospital, November 20, 1941, five hours after the onset of embolism of the second part of the right axillary artery, a rare site. The right hand was painful, pale, and paralyzed. Auricular fibrillation was present. Against his doctor's orders, he had taken no digitalis during the previous six weeks. Dr. A. D. Ryan, of Sodus, New York, had made the diagnosis of embolism and had administered I grain (0.060 Gm.) of papaverine intramuscularly.

Operation: Under local anesthesia an incision was made in the lower third of the arm. Radial pulse was absent, but a pulsation had been felt in the middle of the arm shortly before operation. Exposure revealed the brachial artery pulseless and collapsed. Anesthesia was extended upward into the axilla. The embolus was located at the level of the anterior circumflex humeral artery. Forceful pulsation was felt just above the level of the subscapular artery. This artery was thrombosed at its origin. The long thoracic artery, 1/2 inch above, was pulsating. The anterior circumflex humeral artery was apparently blocked by a bud of the main thrombus, as evidenced by the blue discoloration similar to that in the main artery. This bud was recognized on the thrombus after its removal from the axillary artery. An incision about 2 cm. in length was made over the thrombus. The throm-

Pulvules 3,3'-methylenebis(4-h) droxycoumarin), 50 mg. Furnished by Eli Lilly and Co. for investigational purposes.

caine block of either the stellate ganglion or the lumbar paravertebral sympathetic ganglia may well be done at once. Heparin and dicoumarin should be started as soon as practicable. Alcohol, in 5 cc. amounts for each lumbar ganglion injected, is advisable. It will eliminate the necessity of repeating a maneuver which puts a strain on a seriously ill patient. Evidence of proper placement of the injection is essential before the use of alcohol. The permanence of Horner's syndrome produced when alcohol is used in the neck and the ease of repeated block by the anterior route suggest the use of procaine alone in this region. As will be shown later. sympathetic nerve block may effect a complete re-establishment of the circulation. It will be shown, too, that definite dangers are involved from the standpoint of incorrect interpretation of return of circulation, the error resulting in the loss of the affected part (Case 6). It is to be presumed that the sequence of treatment so far, from the time when the patient was first seen, has not consumed more than two or three hours. We can truly say that time is of the essence in these cases.

General experience indicates that the best results are obtained when embolectomy is performed within eight hours (better less) from the onset of embolism. F. W. Bancroft, however, reports a case in which a successful embolectomy was done forty-eight hours after the first symptoms appeared. This unusual occurrence seems to warrant a revision of our indications for operation so far as the time element is concerned. The condition of the extremity would nevertheless still be the criterion. Damage of the intima is in direct proportion to the length of time an embolus remains attached; coincidentally, the danger of postoperative thrombus formation is in-Heparinization and the use of dicreased. coumarin may minimize this complication.

If the patient cannot move the part, still has pain, and the pallor and blotching have not entirely disappeared within a half-hour following sympathetic block, the final step should be undertaken without delay. By this time the location of the embolus should have been established.

Third Phase: Embolectomy.—Local anesthesia is to be employed; the use of epinephrine in the solution, still recommended by some authors, is distinctly contraindicated. Other anesthetics would endanger an already impaired cardiac function. Most of these patients are in a dangerous condition. A few variants of embolectomy technic, as usually described in the literature, were applied in the cases to be discussed. They are as follows:

1. The use of interrupted sutures rather than a running type of stitch. Clamps (later de-

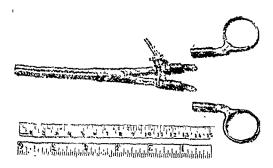

Fig. 1

scribed) are placed above and below the embolus. The artery is incised and the thrombus removed. Sutures of specially prepared arterial silk are now placed about two millimeters apart. Then the clamp, which has been placed on the vessel proximal to the arterial incision is loosened. The distal clamp still being in place, full force of pulsations will be applied to the repaired wall. One or more fine spurts of blood might be seen at this time, issuing between the sutures. These bleeding points are noted and the lower clamp removed. The drop in pressure on the wall of the vessel is now marked by a cessation of active spurting, although there may be active oozing. Both clamps having been reapplied, supplementary sutures, fairly superficial, are placed at the points of spurting previously The importance of avoiding the intima noted is too well known to require comment. method of interrupted suturing has proved completely satisfactory. The side-pressure on the suture line is so markedly lowered, once the distal clamp is removed, that one can feel certain that bleeding is controlled if full pulsation against the previously clamped artery has caused no fine spurts of blood.

2. The use of a soft-bladed, rubber-covered clamp, rather than a spring clip or ligatures, gives better control of the amount of pressure applied to the arterial wall. Figs. 1, 2, and 3, show a clamp which is being developed at this time. With it, graded pressure may be made; removable handles leave the operative field free. The lightest pressure commensurate with adequate hemostasis may be applied with this instrument, serious damage to the intima being thus avoided.

3. Heparinization, begun before operation, seems to have advantages which outweigh the disadvantages of an oozing wound incident to its use. A continuous intravenous drip, started while the patient is being prepared, will aid in the prevention of thrombus formation during the suturing of the artery. Furthermore, some of the solution, being handy, may be injected

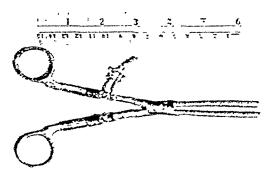

Fig. 2

through the suture line if a tendency to clotting is noted. If heparin is not administered preoperatively, the surgeon may find that a supposedly dry wound becomes a well of tiny arterial "oozers," when the heparin becomes fully effective postoperatively: a troublesome hematoma forms. This occurred in two cases: one in the arm, in which heparin was not given until the operation was completed; and another in which the popliteal space was opened in error and then closed before the femoral embolectomy was done. Here it would have been better to have left the first wound open until circulation had been re-established, thus making it possible to attain meticulous hemostasis, each tiniest bleeder being clamped and tied. Wound healing was perfect in the cases in which heparinization was instituted before the embolectomy was done, and the wound then made surgically dry before closure.

4. Although it is to be presumed that the preoperative sympathetic nerve block has ablated all vasoconstrictor impulses, and that the effect will be lasting if alcohol has been used in addition to procaine, it is still possible that the artery may constrict following the operative manipulations of incision and repair. This occurred in the case of a femoral embolism. At the completion of the arterial suture, pulsation was forceful down to the incision but the artery below the suture line was quiet. A few drops of 1 per cent procaine were injected into the wall of the artery proximal to the repair, just under the external coat, using a small hypodermic needle. Fig. 1

scribed) are placed above and below the embolus. The artery is incised and the thrombus removed. Sutures of specially prepared arterial silk are now placed about two millimeters apart. Then the clamp, which has been placed on the vessel proximal to the arterial incision is loosened. The distal clamp still being in place, full force of pulsations will be applied to the repaired wall. One or more fine spurts of blood might be seen at this time, issuing between the sutures. These bleeding points are noted and the lower clamp removed. The drop in pressure on the wall of the vessel is now marked by a cessation of active spurting, although there may be active oozing. Both clamps having been reapplied, supplementary sutures, fairly superficial, are placed at the points of spurting previously The importance of avoiding the intima is too well known to require comment. method of interrupted suturing has proved completely satisfactory. The side-pressure on the suture line is so markedly lowered, once the distal clamp is removed, that one can feel certain that bleeding is controlled if full pulsation against the previously clamped artery has caused no fine spurts of blood.

2. The use of a soft-bladed, rubber-covered clamp, rather than a spring clip or ligatures, gives better control of the amount of pressure applied to the arterial wall. Figs. 1, 2, and 3, show a clamp which is being developed at this time. With it, graded pressure may be made; removable handles leave the operative field free The lightest pressure commensurate with adequate hemostasis may be applied with this instrument, serious damage to the intima being thus avoided.

3. Heparinization, begun before operation, seems to have advantages which outweigh the disadvantages of an oozing wound incident to its use. A continuous intravenous drip, started while the patient is being prepared, will aid in the prevention of thrombus formation during the suturing of the artery. Furthermore, some of the solution, being handy, may be injected

ompletely. Two grains (0.120 Gm.) of papaverine and been given intramuscularly and heparin beoun at the time of operation. Dicoumarin adninistration was started after ten days of hepariniration. Inexperience can be blamed for this delay. The prothrombin level dropped to 6 per cent of normal and the menstrual flow, which had started after the embolectomy, became hemorrhagic. Drs. F. R. Parker and W. W. Street, in charge during my absence, discontinued dicoumarin and gave 200 cc. of plasma and 1,000 cc. of whole blood to replenish the prothrombin. Bleeding was controlled. The patient had been out of bed and had walked on three successive days when a sudden abdominal pain and diarrhea developed. A tentative diagnosis of mesenteric embolism was made. She died on the following day. Autopsy proved the diagnosis; infarctions were present in the small intestine and kidneys.

## Papaverine Alone

Case 5.—This case, a second admission, is the one instance in which only papaverine was used. It was continued over a period of nine days, 1/z-grain (0.030 Gm.) doses hypodermatically, at first every two hours for four doses, then every four hours for two doses, and then every eight hours for three days. Discontinued for two days, it was again given in the same dosage every two or three hours if the patient was awake. At the end of twenty-four hours, the dose interval was changed to every six hours and thus continued for one day. As before stated, this patient was not seen by me personally but there is no question about the competency of the observations made. There was a steady improvement after the first dose.

# Papaverine-Heparin-Dicoumarin

Case 6 .- M. W., 46-year-old white woman, was admitted to St. Joseph Hospital, March 12, 1942, at 10 A.M. Diagnosis, left popliteal embolism. Her condition was critical. She showed auricular fibrillation, paralysis of foot, loss of sense of touch, both superficial and deep, white skin with purplish mottling, and excruciating pain extending from thigh to toes. No time had been wasted in this case. Her family physician, Dr. J. V. Sheedy, saw her at 9.00 a.m. At 10:00 a.m., 1 grain (0.060 Gm.) of papaverine was injected intramuscularly, and continued subcutaneously in the same dosage at four-hour intervals for four doses, then 1/2 grain (0.030 Gm.) every two hours for eight doses. The administration was thus spread out in the hope that a more sustained vasodilator effect might be attained. As improvement was noted, the doses were spread to four-hour intervals for two days, then every six hours for two days, and then discon-

Continuous venous heparin infusion was not begun until two and a half hours after admission, due to an unavoidable delay. The foot and leg by this time had improved in appearance and temperature, and the patient was able to wiggle the toes slightly. The improvement continued.

This is the first case in which dicoumarin was

given. It was not started until the beginning of the third day, at which time assurance of the safety of administering heparin and dicoumarin synchronously had been given over the telephone by Dr. Ovid O. Meyer, of the University of Wisconsin Medical School.

The initial dose was 350 mg. Then, beginning the next day and continuing for seven days, 100 mg. were given in the morning and 50 mg. at night. The prothrombin percentage averaged 62 per cent, the lowest reading being 25 per cent on the fifth day. It rose to 73 per cent on the sixth day and 88 per cent on the seventh day; the dosage had not been changed. The day following discontinuance it was 71.4 per cent of normal (Smith bedside estimations).

The patient was out of bed on the thirteenth day after admission and went home three days later.

Two months and four days later, she was again admitted. She had been working as a bookkeeper for several weeks. While at work, she was seized with an excruciating pain in both legs and thighs and had severe dyspnea. She was extremely ill. She begged that nothing be done for her except for relief of pain. Diagnosis: Aortic saddle-embolus. She was given papaverine and morphine. Her temperature rose rapidly from 99.4 F. to 105 F. in ten hours, at which time she died.

Case 7.-A. A., a 70-year-old white woman, was admitted to University Hospital at 1:15 P.M. on March 19, 1942. She had been seen by Dr. A. N. Curties in her home twenty-six hours previously. He noted that the left leg was cool, pale, and felt numb to a level 4 inches (10 cm.) above the patella, with red mottling of the skin. Motion of toes and sensation were still present. Bilateral femoral pulsation was present. Left popliteal pulse was absent. His diagnosis at that time was acute occlusion between the bifurcation of the left common iliac artery and the profunda femoris. Examination in the hospital showed a much fainter pulsation of the femoral artery; warmth, however, now extended down to the midcalf. There was a blunted touch sensation and occasional ability to move the foot, less so the toes. The skin of the foot was a bluish white.

Two grains of papaverine (0.120 Gm.) were administered intramuscularly forty-five minutes after admission. This dose was repeated four hours later and then diminished to 1 grain (0.060 Gm.) every four hours and continued for seven doses.

Heparin and dicoumarin were started simultaneously at 2:15 P.M. The heparin was regulated to attain a clotting time of fifteen to twenty minutes. Lee-White clotting time was thirty-five minutes at the end of the first hour. The drop was regulated but the clotting time remained between thirty-five and twenty-four minutes for twenty-four hours, finally holding at an average of about fifteen minutes. Heparin was discontinued at the end of fifty-three hours. The dicoumarin was given in amounts intended to keep the prothrombin at approximately 25 to 50 per cent of normal. The first dose was 0.350 Gm. (seven 50-mg. pulvules), then the following doses at twenty-four-hour inter-

bus arched out of the wound at completion of the incision and free bleeding ensued despite the fact that rubber-covered clamps had been applied above and below the embolic site. This bleeding came from the freed opening of the posterior circumflex humeral artery. The lower end of the thrombus was milked out easily, and was followed by the rest of the clot when the proximal clamp was opened. Loosening the proximal clamp and allowing the forceful ejection of blood to continue for three or four heartbeats gives some assurance that the artery above is cleared of thrombus. This was done in each of the cases here recorded and will not be further mentioned in the case histories. A fine silk atraumatic suture, used in eye operations, was applied in the manner described previously, no special arterial suture being available at the time. It sufficed.

There was still no radial pulse. Inspection of the radial artery at its source showed a blue discoloration indicating the presence of a thrombus. Some color having returned to the hand, along with warmth and motion, it was felt that adequate collateral circulation would occur through the ulnar artery. The radial artery was therefore not opened.

Heparin was started about two and one-half hours after the beginning of the operation. One hour later a radial pulse was noted, bounding in character. Whether heparin was responsible for loosening of the radial thrombus, or solution of it, is conjectural. It has been thought that no such effect was possible. It is here recorded to show that something of the sort must have happened.

Postoperative Course: Three things are to be noted. The first is the formation of an extensive hematoma, requiring drainage by spreading the incision; the second is a severe reaction following blood transfusion on the fourth day. The patient "went wild," required shackling, and was completely irrational. Third, on the tenth day, a phlebitis of the superficial veins of the foot occurred around the area of heparin injection. Heparin was discontinued at this time. The use of dicoumarin will eliminate this complication; it was not infrequent with long-continued use of heparin. The patient was discharged at the end of a month. The heart rate was regular; digitalis had been given since the day following operation. On March 31, 1943, there was perfect function of the right arm and hand. The patient is trying to get a job in the trucking business.

Case 2.—A. H., a 71-year-old white woman, was admitted to St. Joseph Hospital with a diagnosis of perforated peptic ulcer on November 22, 1941. The perforation apparently sealed and the patient's condition improved. Auricular fibrillation had been present for several years. On the fourth day after admission, at 6 a.m., she complained of a sudden sharp pain in the right thigh and leg. The nurse made note of a warm leg, but at 6:45 a.m. she noted "coldness of leg and foot with cyanosis." She was seen at 8:45 a.m. and a diagnosis of popliteal embolism was made. One grain (0.060 Gm.) of papaverine was given intra-

venously. Administration of heparin was started at 10:30 A.M. and the operation was begun at 11:00. Immediately after the arterial repair and removal of the clamps, the patient joyfully reported cessation of the excruciating pain and spoke of the warmth of the foot and her ability to move her toes.

From the viewpoint of re-establishing the circulation and saving the leg, the embolectomy was successful. The patient's general condition, however, gradually deteriorated until her death on the eighth day after operation. There were manifestations of cerebral involvement, probably on an embolic basis.

Case 3.—C. P., a 55-year-old white woman, was admitted to St. Joseph Hospital on February 5, 1942, at 2:00 P.M. At noon she had a severe pain around the left knee joint and numbness of her foot. She continued to work in the kitchen for fifteen minutes but the pain became so severe that her physician (L. W. Ehegartner) was called. Her husband noticed that the foot and leg were cold and white.

One grain (0.060 Gm.) of papaverine was given intramuscularly upon admission to the hospital. Her heart was fibrillating (she had been taking digitalis regularly for three years). Much difficulty was experienced in determining the location of the embolus. At times it was thought that there was pulsation at the proximal end of the popliteal artery. The femoral artery was pulsating forcibly just inferior to the inguinal ligament. It is to be recalled that there is often a strong pulsation just above an embolus, and that this pulsation may be transmitted distally through it. This is the case which has been referred to in preceding comments regarding error in site of incision.

The patient left the hospital on the fifty-third day after admission, the long convalescence being occasioned by the formation of a hematoma which became infected.

She was readmitted nine months later, January 14, 1943, with another embolus, diagnosed as left external iliac. She was given ½ grain (0.030 Gm.) of papaverine every two hours for four doses. The leg was wrapped in cotton-batting dressing, a cradle placed over it, and heat applied. I did not see her during this admission. This report is made through the courtesy of her physician, Dr. J. G. Fred Hiss. Papaverine was continued in ½-grain (0.030 Gm.) doses at varying intervals. There was improvement in the circulation within a short time and she remained well until her discharge fifteen days after admission.

On February 28, 1943, she developed a mesenteric embolism and died two days later.

Case 4.—M. W., a 49-year-old white woman, was admitted to the Syracuse Memorial Hospital on March 27, 1942, at 2:00 p.m. Twelve hours previously she had had pain and loss of function of her right leg. She was mentally confused and somewhat unmanageable, a condition which had been present to some degree following a cerebral embolism six months previously. Two hours after admission, an embolectomy of the right femoral artery was successfully done, the leg regaining its circulation

left undisturbed. The stump healed per primam and the patient left the hospital two weeks thereafter. Her total hospital stay was three and a half months. A popliteal embolectomy should have been done in this case, but patients have the right of refusal.

Case 9 .- M. J., a 63-year-old white woman, was seen by her physician, Dr. R. D. Johnson, three hours before admission to the University Hospital. Pain, pallor, and paralysis of the left foot were noted. Pain extended to the knee. Femoral pulse was present, popliteal absent. One and a half grains (0.090 Gm.) papaverine were given intravenously within a few hours after admission. A left side sympathetic ganglion block was given as described in the previous case. In less than ten minutes after the block, the patient moved her foot and toes. The light purplish mottling increased for about one-half hour and then disappeared. afflicted foot was even warmer than the opposite one. Heparin was discontinued in twenty-four hours. Dicoumarin, which had been started on admission, was given as follows: January 29—250 mg.; January 30—200 mg.; January 31—100 mg.; February 2—50 mg.; February 3—none; February 3 ary 4-50 mg. Prothrombin percentages on the corresponding days were 77.1, 43.7, 29, 26.5, (next day 15.3), 25.8.

Papaverine was continued for five days in ½-grain (0.030 Gm.) doses every three hours. (Note length of time and total dosage.) Digitalization was begun under the direction of Dr. Johnson. The patient had been extremely uncooperative regarding this medication over a period of weeks before the present illness. She made an excellent recovery, was out of bed on the tenth day, and went home on the thirteenth day after admission.

Case 10.—C. J., a 69-year-old white woman, was admitted to the medical ward service of the University Hospital at 11:00 A.M. on March 27, 1943. Her present illness had begun with what was apparently an embolic episode in the right leg two weeks before, with recovery. Seventeen hours before admission she had had a severe pain and coldness of both legs, finally shifting entirely to the right lower extremity. She was transferred to the surgical service and was seen shortly after admission. There was a persistent cough with extreme dyspnea. Her condition was extremely precarious. A note, made when she was seen personally at 3:45 P.M. reads: "Arterial embolism, right popliteal. Arteriolar spasm, probably reflex, right leg. Oscillations distinct in left leg, absent in right leg (below knee). Both femoral arteries pulsating. Pulsation in right femoral seems to extend down to the profunda femoris, indicating patency rather than transmission of a proximal pulse through a thrombus. Sensation and movement normal in the left leg. Sensation dulled and movement limited to great toe, on right side. Skin of right foot blue-splotched. Apparently, lumbar ganglion block, given two and a half hours before (by resident), has had no effect. Seventeen and one-half hours before lumbar block and twenty-two hours at this time, papaverine, heparin, and dicoumarin therapy were started. The general condition of the patient and length of elapsed time are against consideration of embolectomy."

Drug dosage paralleled that given in the previous case but was without effect. The prothrombin level averaged 30 per cent for nine days. It is interesting to note that the level stayed below 39 per cent for six days after the dicoumarin was discontinued. At this time, amputation being contemplated, 500 cc. of whole fresh blood and 1,000 cc. of dilute bank blood were given to furnish prothrombin. The level rose to 79.9 per cent on the eighth day after admission. A midthigh amputation was done by the House Staff on the following day.

A Callandar amputation was begun but because of thrombosis of the popliteal artery, as diagnosed, the operators decided to remove the clot until active spurting of blood occurred. This necessitated a higher ligation and then a midthigh amputation. Fear of poor healing of the stump led to this decision. Gangrene of the leg was demarcated at the upper third of the leg. The Callender operation was eminently successful in the counterpart of this situation in Case 6.

The patient's condition gradually deteriorated and she died twelve days later. Anatomic diagnoses, postmortem: arteriosclerotic heart disease; mural thrombi left auricle; old and recent infarcts of right leg, spleen, and kidney; old myocardial infarction, recent coronary thrombosis, acute cystitis; pulmonary embolism; pulmonary thrombosis; pulmonary emphysema, and bilateral thrombosis of iliac veins.

## Summary

Once diagnosed, arterial embolism of the extremities demands immediate and uninterrupted treatment. This treatment may be divided into three phases. In the first one, papaverine is given by the attending physician, either intravenously or intramuscularly. During this phase the patient is moved to a hospital. The diagnosis of site of embolic lodgment is established. Occasionally the treatment with papaverine will be sufficient of itself. If improvement is questionable, the second phase is instituted by the use of heparin, dicoumarin, and sympathetic ganglion block. Not longer than an hour should elapse during this phase after completion of the ganglion block. Observation must be continuous until circulation is definitely established. Unless there is incontrovertible evidence of return of circulation, embolectomy is indicated.

Impressions gained by analysis of four embolectomies:

1. There was no indication that heparin infusion, started shortly before operation, is dangerous. On the contrary, its use should prevent a false sense of security regarding complete hemostasis before closure. Tiny oozing vessels, which ordinarily give no trouble, begin to bleed once the heparin effect is established. Trouble-some hematoma may result if the heparin is not

vals for six days: 0.200 Gm.; 0.200 Gm.; 0.200 Gm.; 0.250 Gm.; 0.350 Gm.; 0.200 Gm.

The importance of close cooperation between the laboratory and the clinician is illustrated in this case. Both physician and technician should be fully informed regarding methods of a technic new to both. The large doses of dicoumarin were not necessary, nor, in the light of further experience, was it necessary to give heparin for fifty-three hours. The first report on the prothrombin percentage (105 per cent) was made forty-four hours after institution of dicoumarin therapy. No report was made the following day, which was Sunday. Then the percentage was 99 per cent, 108 per cent, 110 per cent, at twenty-four-hour intervals. that something was wrong, the technician, who had made the estimations in Case 4, was called in. Venom had been used in the first estimations and the blood had been carried to another hospital for examination. Either the time loss or a deteriorated venom was at fault. The method itself is reliable. Using the Smith bedside method, the percentage was found to be 45.3 as against the 108 per cent recorded a few hours before by the venom method. The patient had been given 350 mg. of dicoumarin in the light of the reading of 99 per cent. The next day the Smith reading was 23.2 per cent while the other was 110 per cent Dicoumarin was discontinued. Twenty-four-hour interval estimations after that were 15 per cent, 12 per cent, 52 per cent, and then another, four days later, 98 per cent. Fortunately no spontaneous hemorrhage occurred. Ecchymosis was marked over both deltoids, into which the papaverine had been injected, and around the vein into which the heparin had been infused. The patient was discharged on the thirteenth day after admission, with a normally functioning foot and leg.

## Sympathetic Ganglion Block Plus Papaverine, Heparin, and Dicoumarin

It will be noted that about a year elapsed before the following groups of cases presented themselves. Whether the northern winter is a causative factor in extremity embolism is conjectural. A survey of this factor, at another time, should be of interest. The groups here reported were seen from November to March.

In a personal conversation with Dr. Alton Ochsner, professor of surgery at Tulane University School of Medicine, in April, 1942, the thought was expressed by him that sympathetic ganglion block should without exception obviate the need for embolectomy. Having Dr. Ochsner's wide experience with this method of treatment in mind, the decision was made to give sympathetic ganglion block a trial. As will be seen, it worked brilliantly in one case and failed in two. In the two failures, a fair analysis would include the possibility that the block was improperly placed. One of them (Case 7) was done by me, and Case 9 by members of a surgical Resident

Staff. In the one I handled, it will be noted that improvement occurred up to a certain point, then deterioration. Case 9, except for a slight increase in warmth to midcalf, showed no improvement at any time. In each of the following cases auricular fibrillation was present. Although digitalis had been taken previously, it had been discontinued by the patient in Cases 7 and 8, against orders, and in Case 9 because of digitalis intorication, which had occurred five months previously while the patient was on medical service.

Case 8.—M. D., a 64-year-old white woman, was examined at 12:30 p.m. on January 13, 1943, in the Syracuse University Hospital. At 5:30 a.m. she had noticed a terrific burning sensation along the back of her right calf and numbness in the foot She was unable to move the foot.

A diagnosis of embolism was made by her physician, Dr. J. R. Kallet, at 6.00 A.M. The patient refused to go to a hospital at that time. This occasioned a delay of six hours. Pulsations were absent in the right femoral and popliteal arteries at 12:30 P.M. The leg was cold to a point just above the knee. The left leg was normal. A diagnosis of embolism of the right common iliac artery was made. The patient and her family would not consider an operation but lumbar sympathetic ganglior block was accepted. Papaverine was administered in 1/2-grain (0.030 Gm.) doses, beginning immedi ately and continued for six doses at three-hour intervals. Heparin and dicoumarin were started Digitalis therapy was begun under the direction of Dr. A. N. Curtiss.

At 2:15 P.M., the sympathetic ganglion block had been completed. Ten ce, each of 1 per cent procaine solution had been injected into the twelft thoracic and first and second lumbar gangla, fo lowed in five minutes by the injection of 5 cc. of 9 per cent alcohol through each of three needle which had been left in place. Femoral pulsatio had returned at the end of two hours; the leg wa warm to a point just above the ankle, and deepressure sense had returned to the medial side of the foot. Thermocouple readings indicated that circulation might become completely re-established This proved to be a false lead.

As days passed, it became apparent that necrosi was supervening in the great, second, and fourtl toes, and the lateral half of the dorsum of the foot as well as in a small area on the lateral side of the lower third of the leg. The leg became edematou and painful. These findings, however, were not completely present until a month after admission Because of the hope that palliative treatment might save the foot, although it was paralyzed, and at the patient's insistence on further trial, another month of dressing treatment ensued. Then, with x-ray findings of damage in the first, second, fourth and fifth metatarsals, amputation at the knee was suggested and accepted. A modified Callander amputation was done under local anesthesia. The popliteal artery was found to be completely blocked by a thrombus. It was tied and severed, the thrombus left undisturbed. The stump healed per primam and the patient left the hospital two weeks thereafter. Her total hospital stay was three and a half months. A popliteal embolectomy should have been done in this case, but patients have the right of refusal.

Case 9 .- M. J., a 63-year-old white woman, was seen by her physician, Dr. R. D. Johnson, three hours before admission to the University Hospital. Pain, pallor, and paralysis of the left foot were noted. Pain extended to the knee. Femoral pulse was present, popliteal absent. One and a half grains (0.090 Gm.) papaverine were given intravenously within a few hours after admission. A left side sympathetic ganglion block was given as described in the previous case. In less than ten minutes after the block, the patient moved her foot and toes. The light purplish mottling increased for about one-half hour and then disappeared. afflicted foot was even warmer than the opposite one. Heparin was discontinued in twenty-four hours. Dicoumarin, which had been started on admission, was given as follows: January 29-250 mg.; January 30-200 mg.; January 31—100 mg.; February 2-50 mg.; February 3-none; February 4-50 mg. Prothrombin percentages on the corresponding days were 77.1, 43.7, 29, 26.5, (next day 15.3), 25.8.

Papaverine was continued for five days in ½-grain (0.030 Gm.) doses every three hours. (Note length of time and total dosage.) Digitalization was begun under the direction of Dr. Johnson. The patient had been extremely uncooperative regarding this medication over a period of weeks before the present illness. She made an excellent recovery, was out of bed on the tenth day, and went home on the thirteenth day after admission.

Case 10.—C. J., a 69-year-old white woman, was admitted to the medical ward service of the University Hospital at 11:00 A.M. on March 27, 1943. Her present illness had begun with what was apparently an embolic episode in the right leg two weeks before, with recovery. Seventeen hours before admission she had had a severe pain and coldness of both legs, finally shifting entirely to the right lower extremity. She was transferred to the surgical service and was seen shortly after admission. There was a persistent cough with extreme dyspnea. Her condition was extremely precarious. A note, made when she was seen personally at 3:45 P.M. reads: "Arterial embolism, right popliteal. Arteriolar spasm, probably reflex, right leg. Oscillations distinct in left leg, absent in right leg (below knee). Both femoral arteries pulsating. Pulsation in right femoral seems to extend down to the profunda femoris, indicating patency rather than transmission of a proximal pulse through a thrombus. Sensation and movement normal in the left leg. Sensation dulled and movement limited to great toe, on right side. Skin of right foot blue-splotched. Apparently, lumbar ganglion block, given two and a half hours before (by resident), has had no effect. Seventeen and one-half hours before lumbar block and twenty-two hours at this time, papaverine, heparin, and dicoumarin therapy were started. The general condition of the patient and length of elapsed time are against consideration of embolectomy."

Drug dosage paralleled that given in the previous case but was without effect. The prothrombin level averaged 30 per cent for nine days. It is interesting to note that the level stayed below 39 per cent for six days after the dicoumarin was discontinued. At this time, amputation being contemplated, 500 cc. of whole fresh blood and 1,000 cc. of dilute bank blood were given to furnish prothrombin. The level rose to 79.9 per cent on the eighth day after admission. A midthigh amputation was done by the House Staff on the following day.

A Callandar amputation was begun but because of thrombosis of the popliteal artery, as diagnosed, the operators decided to remove the clot until active spurting of blood occurred. This necessitated a higher ligation and then a midthigh amputation. Fear of poor healing of the stump led to this decision. Gangrene of the leg was demarcated at the upper third of the leg. The Callender operation was eminently successful in the counterpart of this situation in Case 6.

The patient's condition gradually deteriorated and she died twelve days later. Anatomic diagnoses, postmortem: arteriosclerotic heart disease; mural thrombi left auricle; old and recent infarcts of right leg, spleen, and kidney; old myocardial infarction, recent coronary thrombosis, acute cystitis; pulmonary embolism; pulmonary thrombosis; pulmonary emphysema, and bilateral thrombosis of iliac veins.

## Summary

Once diagnosed, arterial embolism of the extremities demands immediate and uninterrupted treatment. This treatment may be divided into three phases. In the first one, papaverine is given by the attending physician, either intravenously or intramuscularly. During this phase the patient is moved to a hospital. The diagnosis of site of embolic lodgment is established. Occasionally the treatment with papaverine will be sufficient of itself. If improvement is questionable, the second phase is instituted by the use of heparin, dicoumarin, and sympathetic ganglion block. Not longer than an hour should elapse during this phase after completion of the ganglion block. Observation must be continuous until circulation is definitely established. Unless there is incontrovertible evidence of return of circulation, embolectomy is indicated.

Impressions gained by analysis of four embolectomies:

1. There was no indication that heparin infusion, started shortly before operation, is dangerous. On the contrary, its use should prevent a false sense of security regarding complete hemostasis before closure. Tiny oozing vessels, which ordinarily give no trouble, begin to bleed once the heparin effect is established. Troublesome hematoma may result if the heparin is not

given until after the wound is closed. Such oozing can be seen and stopped when heparin effect is present at the time of operation.

- 2. Injection of procaine under the external coat of the artery, above and below the incision, acts much like a periarterial sympathectomy. Its routine use should be a valuable adjunct as a preventive of vasospasm during and after the repair.
- 3. Interrupted sutures are satisfactory in repair of arterial incisions.
- 4. A method of hemostasis, with minimal risk of damage to the intima, is afforded by the use of a thin-bladed, rubber-covered clamp which

can be closed to any desired pressure. Removable handles keep the wound free of unnecessary encumbrances.

At least one surgeon in every community should perfect himself in the technic of embolectomy. The physician should get the patient to a hospital without undue loss of time.

## PARALYSIS FUND-RAISING APPEAL SET

January 14 to 31, inclusive, will mark the official period for the 1944 fund-raising appeal of the National Foundation for Infantile Paralysis, through the celebration of the President's birthday.

the celebration of the President's birthday.

Ever since the dedication of that day in 1934 by President Roosevelt to the fight against infantile paralysis, the American people have taken this cause of the children to their heart. They have responded in such full measure that this year—when the United States experienced the most severe polio epidemic since 1931—we were able to strike back hard at the crippler and ward off what threatened to be a vital blow at America's all-out war effort.

Unfortunately, infantile paralysis can and will strike again. We do not know what 1944 may hold for our nation in the way of epidemics. But we do know that this year its ravages were felt deeply at such widely divergent points as Texas and Connecticut, California and Kansas, Oklahoma and Oregon, as well as Utah, Washington, and Illinois.

Our duty is manifest. We must see to it that the

Our duty is manifest. We must see to it that the funds upon which such heavy inroads were made by the 1943 epidemic are replenished and enlarged to provide a margin of relief and safety for those whom paralysis has struck or may strike in the near future.

It is particularly heartening therefore to report at this time that the formation of our fund-raising organization for the 1944 Appeal is nearing completion throughout the country and in Alaska, Panama, the Virgin Islands, and Hawaii.

Thanks to the splendid cooperation of our State Birthday Celebration chairmen the setting up of our fund-raising program for 1944 has been greatly expedited. Never before in the history of the National Foundation, Director of Organization D. Walker Wear, points out, has a more favorable start been made toward a highly successful campaign.

Missouri State Birthday Celebration Chairman Robert T. Hensley was the first to send in the names of county chairmen appointees; while Arizona, under the direction of Terrence A. Carson, captures the honor of being the first state in the union to report a fully completed organization.

Word of the appointment of county and city campaign chairmen continues to reach our office with every mail, testifying not only to the zeal of the state chairmen but also to the manner in which the leading men and women throughout the country respond to the invitation to serve in their areas as

#### FOR JANUARY 14-31

front-line fighters in this continuing battle against infantile paralysis.

Successful campaigns do not spring up overnight. They are the result of comprehensive planning and the cooperative execution of those plans. Under today's conditions, with the impact of the war being felt in every community, it is especially necessary for us to wage a streamlined campaign based on our policy of "economy, sincerity, efficiency, and simplicity."

The keynote word "economy" should be kept well in mind. Regardless of how successful our 1944 campaign will be—and the toll of this summer's epidemic makes mandatory the topping of last year's results—we cannot afford to waste one iota

of the amount raised.

The 1944 "Campaign Handbook" is now on the press and will soon be sent to our Birthday Celebration chairmen. The book is a source of helpful information and will serve as a ready-reference aid in setting up to the fullest degree the efficiently functioning fund-raising organizations which will put the campaign over the top.

In this connection the value of close cooperation between campaign and chapter chairmen cannot be too strongly emphasized. Our chapters have done a magnificent job in meeting the demands levied by the recent polio epidemic. Birthday Celebration chairmen will find the chapters eager to aid in every possible way during the campaign period.

Throughout the country many of our chapter officers already are preparing the groundwork for campaign activities. Among them is Miss Catherine C. Gaule, assistant secretary of the Maryland State Chapter. Sometime ago she secured volunteer workers to assist in listing names and addresses from the telephone books of her area and addressing envelopes in which the President's birthday greeting cards will be inserted.

James F. Arbuckle, executive secretary of the Westchester County (New York) Chapter, has been active throughout the summer not only in immediate chapter affairs but has been contacting war plants in his county and arranging for labor's participation in the 1944 campaign.

Time saved in this fashion is doubly valuable. And if the fight against infantile paralysis is to continue successfully it is up to all of us to see to it that the 1944 fund-raising appeal tops all previous records.—National Foundati

## TECHNICAL PRECISION IN THYROID SURGERY

CHAS. GORDON HEYD, M.D., F.A.C.S., D.M.Sc., New York City

FOR technical precision in thyroid surgery four essentials are required: (1) a reverse Trendelenburg position on the operating table, (2) a safe, efficient anesthesia, (3) the absolute control of hemorrhage, and (4) the complete exposure of the entire operative field.

## Preparation of the Patient

The position of the patient on the operating table is of great surgical importance. With the patient in the dorsal position, a sandbag approximately 15 inches in length and 4 inches in diameter is placed transversely under both shoulders and well below the level of the seventh cervical vertebra. The sandbag, plus the raising or lowering of the headrest, allows full extension of the neck without undue traction or tension. The patient is then raised into a reverse Trendelenburg position of about 45 degrees. The feet are supported by the footrest and the patient is held on the table by a surcingle applied across the thighs just above the knees. After the patient is placed in this position, the draping of the patient is simple. The operative field is sterilized with 31/2 per cent tincture of iodine, applied to the anterior three-fourths of the neck from the lower jaw downward onto the chest to a level just above the transverse nipple line. sterile towels moistened with saline solution are wrung "dry" and crushed into a rather loose balllike mass. These are placed one on each side of the patient's neck between the shoulder and the mastoid process. Four dry sterile towels are now arranged as follows: (1) one transversely across the chest at about the level of the second rib, (2) one on each side, placed longitudinally and extending downward with their inner edge about level with the midpoint of the sternomastoid muscle, (3) and the fourth folded once on its longitudinal axis, with the folded edge draped transversely just below the chin and held in position by three towel clamps. One clamp is apphed in the midline just below the symphysis and one clamp on each side is applied to the skin just behind the angle of the lower jaw and in front of the lobule of the ear. The two lateral towel clamps also grasp the underlying sterile towel on each side. The upper leaf of the transverse sterile towel is now elevated over the patient's chin and face, and the anesthetist places his hand between the two layers of the towel and holds the patient's jaw. The lower leaf of this towel is then brought up over the hand of the anesthetist and is thereby completely excluded from the operative field. A quadrilateral space is thus exposed, bounded by four sterile towels. A laparotomy sheet with a large aperture in the center is placed over the head of the patient and the anesthetist, and attached to the usual circular headguard of the operating table, so that the hole in the laparotomy sheet is directly over the operative field. The anesthetist and the anesthetist's hand are entirely outside the operative field. If it becomes necessary, during the course of the operation, to perform artificial respiration or intratracheal manipulations, the upper half of the laparotomy sheet can be brought down over the patient's chest and the sterility of the operating field can be continuously maintained.

#### Anesthesia

A safe, simple, and adequate anesthesia is essential. It is desirable to have the patient brought to the operating room in a semisomnolent condition. The patient is given a cleansing enema the afternoon of the day before the operation, and about 9:00 P.M. of the evening of the same day he is given nembutal, 3/4 grain or 11/2 grains. The next morning, about one hour and fifteen minutes before the scheduled time of operation, a solution of paraldehyde in thin starch water is given by rectum—one cc. of paraldehyde is given per 10 pounds of body weight. If the patient is underweight (from 90 to 120 pounds) a minimum of 12 cc. of paraldehyde is given. If the patient is obese and heavy, a maximum of 16 cc. of paraldehyde is given. The paraldehyde is given in 150 cc. of thin starch water. starch water is prepared as follows: 1 tablespoonful of starch (cornstarch) to 1 pint of cold water; stir water with starch, heat slowly, stirring until it comes to a full boil.

One-half hour before operation and forty-five minutes after the paraldehyde solution has been introduced into the rectum, the patient is given a hypodermic of morphine sulfate, ½ grain, and scopolamine hydrobromide, ½ grain. Unless some of the paraldehyde solution is expelled, the patient is usually asleep by the time of his arrival in the operating room. The sleep is not deep, for the patient may be aroused on being spoken to or by changing his position on the operating table. Ordinarily the patient has no recollection of the trip to the operating room or of the operation. By this somnolence the preoperative tachycardia from tension and the trip to the operating room, etc., is avoided. After the pa-

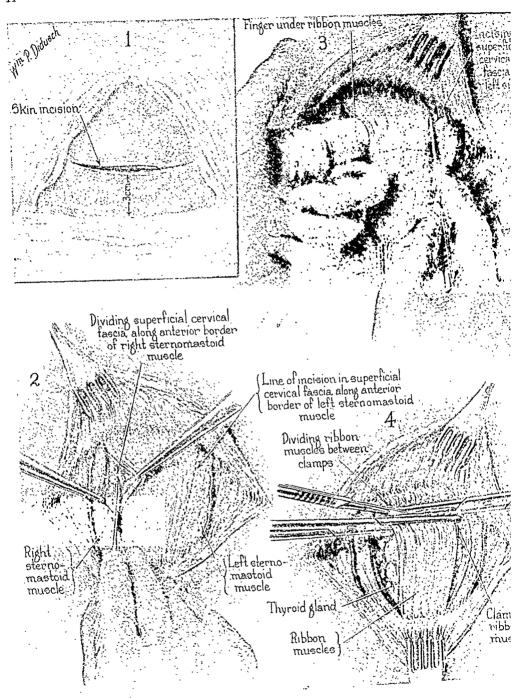

PLATE 1.

tient is placed in position on the operating table, ethylene-gas anesthesia is induced.

Operation The skin incision should always be considered from the point of view of the ultimate scar

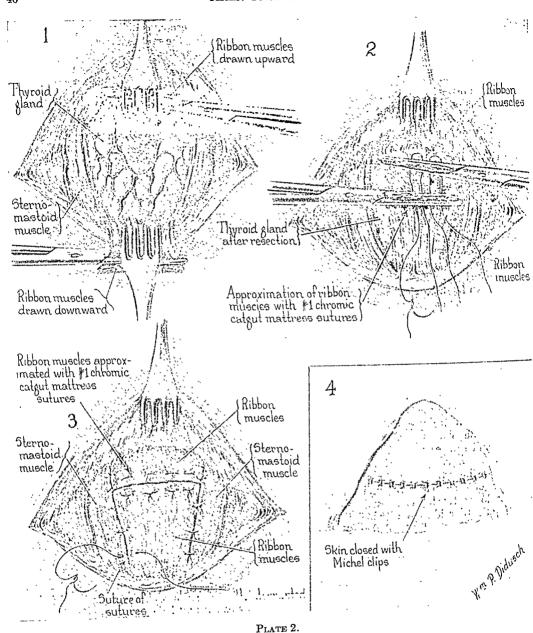

(Plate 1, Fig. 1). All thyroid incisions t be pulled or displaced downward into the part of the chest. With a neck of norms tour, the lowest point of the incision should less than 2 or 3 cm. above the sternal This incision, within a year, will descend a 1 cm. A scar lower than this cannot be covered by beads or a necklace. If the neck is enlarged, as it usually is, and asymmetrical in contour, as it usually is, the incision should be placed somewhat higher on the side of the neck that has the greater protuberance, for the descent of the scar will be greater on that side. Before beginning the skin incision, it is our custom to "saw" rapidly with a thread across the greatest anterior protrusion of the thyroid and to make the skin incision either above, through, or below the "red line" made by the thread, depending on the general shape, size, and asymmetry of the goiter.

The incision is carried down to but not through the platysma and the upper and lower flaps are developed. The lower flap is first undermined to a depth of about 1 to 2 cm.; it is usually not necessary to undermine deeper, for this will be sufficient to permit ease of coaptation in the closure of the skin wound. If the undermining is carried down further, it offers a dependent space for the collection of serum after operation. upper flap, however, is dissected upward for a considerable distance, at least above the thyroid promontory. Hemostasis is completed before any further operative procedure is carried out. A four-prong hook retractor is placed at the midpoint of the upper flap and held in the median line by the second assistant. The space between the hyoid bone and the sternum is occupied by a superficial group of two muscles, the sternohyoid and the omohyoid, and beneath these there is a broader and shorter muscle, the sternothyroid. These three muscles are called the ribbon muscles and all are innervated by the ansa hypoglossi, the fibers of which enter the individual muscles in their lower third. The usual procedure for exposing the thyroid gland is to incise the cervical fascia in the median line and then to divide the ribbon muscles on either side by applying two crushing clamps at approximately the upper third. When this procedure is completed, it is possible by traction upward and downward of the divided muscle groups, together with lateral traction, to obtain a fairly good but incomplete exposure of either side.

In the course of our experience we began to simplify this bilateral procedure by dividing both lateral groups of ribbon muscles—right and left—between two clamps, thus giving a larger and more ample exposure and leaving the operative field less encumbered, with two clamps instead of four. In addition, the goiter and thyroid gland are visualized in their entirety. With the surgeon standing on the right side of the patient, the superficial cervical fascia is divided along the anterior border of the right sternomastoid muscle for a distance of 7 to 10 cm. (Plate 1, Fig. 2). A Parker retractor is introduced and the fleshy

body of the sternomastoid muscle is pulled outward, exposing the pretracheal fascia as it moves forward from the carotid sheath to the midline. The upper belly of the omohyoid muscles will be plainly visible, transversing this space from the hvoid bone downward and outward toward the The omohyoid can usually be retracted unward. The pretracheal fascia is incised, more or less paralleling the incision along the anterior border of the right sternomastoid. The sternothyroid muscle is readily identified and its external lateral edge is picked up with thumb forceps and incised from above downward. The index finger of the left hand can then be insinuated beneath the three ribbon muscles on the right side with the palmar surface of the finger passing anteriorly over the thyroid gland and trachea. The left finger passes readily beyond the median line under the left group of ribbon muscles. The index finger is then turned so that the palmar surface is turned upward and the same incisions are made on the left side at the anterior border of the left sternomastoid muscle (Plate 1, Fig. 3). The index finger of the right hand is inserted into the cleft thus made so that there are underneath both groups of ribbon muscles—the left and right—the index finger of the left hand and the index finger of the right hand. The muscles are raised off the isthmus of the thyroid and two Kocher clamps are applied as follows: the first assistant, standing on the patient's left side and opposite the operator, inserts the upper Kocher clamp from the patient's left to right side and the operator inserts the lower Kocher clamp from the patient's right to left side: the handles of the Kocher clamps are thus placed one on each side of the patient and the two clamps are applied at approximately the junction of the upper and middle third of the muscle group (Plate 1, Fig. 4). The muscles are then divided and, with a hook retractor placed under each clamp, traction is made upward and downward, and the entire thyroid area is fully exposed (Plate

In the resection of the thyroid gland there are four procedures of great technical value: (1) the clamping and division of the lateral thyroid vein, (2) the mobilization and division of the superior pole, (3) the undermining and division of the isthmus in the median line, and (4) the recognition of the inferior thyroid artery and its division close to or within the substance of the gland. After the exposure has been made as outlined, the surgeon, standing on the right side, begins the resection by grasping, with Kocher goiter clamps, the anterior surface of the right lobe of the thyroid a few centimeters below the superior pole. By slight traction upward and toward the median line the right lobe is lifted out of its bed

By blunt dissection the lateral vein comes into view. This vessel is clamped and ligated. The division of the lateral vein allows a considerable degree of mobilization of the lobe in an anteroposterior direction. The next step is to ligate and divide the superior pole. The superior thyroid artery and vein lie upon the antero-inner surface of the gland and supply about two-thirds of the blood supply to the anterior and mesial surface of the lobe. A goiter clamp grasps the thyroid a few centimeters below the upper limit of the superior pole and with blunt dissection the superior thyroid vessels

are developed. A second goiter clamp is now applied to the superior pole but behind the superior thyroid vessels, and the superior pole is readily mobilized from behind the vessels into the field. As the superior thyroid vessels, artery, and veins come from above downward and rest on the superior pole it is very easy to enucleate the superior pole from behind the vessels and by so doing to leave the artery and veins clear and free from thyroid tissue. The effect of this maneuver is to bring the superior thyroid vessels into prominence and allows their being ligated at the beginning of

the resection, without any danger of including the superior larvngeal nerve in the ligature. With the superior pole and the lateral vein divided, the lobe is freely movable except for the isthmus. The isthmus is undermined in the median line and divided. Hemostasis is assured temporarily by using curved crushing clamps on either side of the midline of the isthmus. The lobe, freed from its isthmal attachment, is now freely movable except for the inferior thyroid vessels. The inferior thyroid artery enters the gland in a transverse direction at about the junction of the middle and lower third of the gland. By blunt dissection, the inferior thyroid artery is exposed and isolated, and ligated separately just as it enters the thyroid tissue. The recurrent laryngeal nerve is always in some anatomic juxtaposition to the inferior thyroid artery and by separation, isolation, and ligation of the artery in thyroid tissue the nerve is uninjured and usually exposed. The surgeon by this time has a freely movable lobe and with the second finger of the left hand pressing against the gland and his thumb and first finger holding one or two Kocher clamps applied to the divided isthmus, resection begins from the midline outward. All incisions are made only after hemostats are applied. The vessels are ligated, using No. 0 plain catgut. The edge of the posterior capsule with a remnant of thyroid tissue is approximated to the tracheal tissue by interrupted sutures of No. 0 plain catgut. Hemostasis must be complete and absolute before resection of the other side is attempted or the wound is closed.

If only a hemisection is performed, the operation is terminated at this point. If a bilateral subtotal resection is carried out, the other side is completed in exactly the same manner by the operator leaving the right side of the patient and moving over to the left side.

With the above exposure and technic, postoperative hemorrhage of any degree has not been a factor in the postoperative care, but the accumulation of a small amount of blood or serum in one or both sides of the thyroid space after operation will produce increasing laryngeal difficulty and strangulation. It requires but a relatively small amount of fluid retained in the space formerly occupied by the thyroid, and under the pressure of the flap muscles, to produce an alarming disability in breathing. It has been necessary to reopen the thyroid wound in three cases out of a total personal experience of about 900 operative cases. The signs of this impending danger are readily recognized. Immediately after the operation the patient recovers from the ethylene anesthesia rapidly and is encouraged to respond to direct questions. The voice sounds are then noted and recorded on the patient's chart. In the course of a couple of hours the patient's

breathing is accompanied by noisy inspiration in contrast to an almost noiseless expiration. Very soon the patient's voice becomes harshand brassy. Interference with the laryngeal nerve mechanism is imminent. When this condition intervenes. the following procedures are carried out: the Michel clips are removed from the skin wound and the skin flaps are elevated and kept elevated by sterile gauze packing. At the end of an hour the skin flaps are elevated completely and the sutures uniting the divided ribbon muscles are all divided. The ribbon muscles are then gently deflected upward and downward and some sterile gauze is lightly introduced beneath them. These graded procedures will effectively decompress the thyroid space and the picture will gradually change to one of betterment. At the end of twenty-four hours the packing is removed, and ordinarily the wound is allowed to granulate for four or five days, when a secondary suture is carried out. This graded procedure avoids the traumatizing effect of reoperation and is performed in the patient's room without anesthesia. It has been uniformly successful in our cases. It has been necessary to do a tracheotomy only twice; on both occasions the tracheotomy was performed at the time of the thyroid resection. One was a case of Reidel's struma and the other a difficult malignant goiter.

The question of drainage is always a difficult matter. It has been our custom, when only one side is operated upon and the thyroid tumor is relatively moderate in size and the hemostasis complete, to close the wound without drainage. It is well to remember that an individual who has been sensitized by long-continued hyperthyroidism is hypersensitized to serum protein and any operation for thyroidism will occasion the absorption of serum from the thyroid wounds.

If drainage seems indicated, a latex drain is inserted in one or both of the thyroid fossae and brought out of the wound at about the midpoint of the sternomastoid muscles and never emerges from the center of the wound or over the trachea.

At the termination of the resection of the thyroid the retractors are removed and the muscle groups approximated and united by three or four interrupted mattress sutures of No. 1 chromic catgut (Plate 2, Figs. 2 and 3). The closure of the wound is practically an anatomic reconstruction in the natural plane of musculature and the skin is closed by Michel clips (Plate 2, Fig. 4). One-half, or every other one, of the Michel clips is removed at the end of forty-eight hours, and at the point of removal of the Michel clip a small strip of sterile adhesive plaster, 1 inch in length and 1/4 inch in width, is placed over the skin edge to splint the wound. All the Michel clips are removed by the end of seventy-two hours and the

drains, if used, are also removed at the end of the first twenty-four hours.

The preoperative preparation of patients about to undergo a thyroid resection has been very much simplified during the last few years. It is our custom to put the patients to bed and impose absolute bed rest for a number of days before operation. The patient is put upon a high caloric diet, with protein at least twice a day, and an intravenous infusion of 1,000 cc. of normal saline plus 5 per cent dextrose, and 7 grains of sodium iodide is given daily. A cloth-enclosed icebag is placed over the heart and thyroid area at alternate hours from 9:00 A.M. to 6:00 P.M. cathartics are given but the colon is emptied each day with a milk-and-molasses enema of 14 ounces. Sedation is given in the form of 3/4 grain of luminal or nembutal three or four times a day. When it is economically possible we try to place the patient in a single room with no other occupants and limit both the number of visitors and the duration of their visits. A single basal metabolism test is taken a few days preceding the operation and that is the only determination we employ until sometime after the surgery has been performed.

With the above regimen we also are in the habit of giving the patient—if the patient has not been taking iodine—7 to 10 drops of saturated solution of sodium iodide in a glass of water after each meal. We also try to have the patient take at least 4 or 5 glasses of fluid a day, in addition to the fluid taken with meals.

It is gratifying to observe the almost uniform clinical improvement with this regimen of preoperative treatment. The determination as to

when the patient is ready for surgery is based upon the general appraisal of the improvement accomplished by the above therapy. In patients in whom the cardiac symptoms are most prominent we employ limited exercise as a means of determining the relative cardiac improvement. After four or five days of absolute bed rest the patient is permitted to get out of bed, sit in a chair for an hour, and do a little walking. The pulse is taken one-half hour before his getting out of bed, then one-half hour and an hour after he is up. After one hour the patient returns to bed. The pulse is then taken and is taken again one-half hour later and one hour later. If the pulse returns to the same rate within an hour after the patient returns to bed as it was before he got up, we feel that the heart has shown substantial improvement both in cardiac output and cardiac reserve. We believe this simple test will indicate a cardiac mechanism that will enable the patient to undergo successfully either a subtotal hemisection or a bilateral subtotal resection. We employ digitalis rather infrequently and never fully digitalize a patient. At most 11/2 grains of digitalis are given twice a day.

The postoperative treatment is almost exactly the same as the preoperative treatment.\*

## BRIGHTER OUTLOOK FOR VICTIMS OF

The life expectancy after angina pectoris (breast pang) first appears is about twice as long as has been commonly believed, Paul D. White, M.D., Edward F. Bland, M.D., Boston, and Edward W. Miskall, M.D., East Liverpool, Ohio, report in the Journal of the American Medical Association for November 27. This statement is based on what is, so far as they know, the first study of this condition that involved a large series of cases followed over an adequate length of time.

The three physicians made a follow-up study in 1943 of 497 cases of angina pectoris that were first observed in the years from 1920 to 1930. Of the 497 patients, they say, "445 are dead and 52 are still living. The average duration to death of the 445 was 7.9 years, while the average duration from onset of the disease in the living is 18.4 years. The average duration to date for the combined dead and living is 9 years, which will ultimately increase when all the present survivors succumb, doubtless to a figure approximating ten years, a duration of life about double that at present widely regarded as the expectation of life after angina

## ANGINA PECTORIS

pectoris first appears (five years or less). Seventy-six per cent of the deaths were due to cardiac causes.

A pronounced degree of nervous sensibility was a favorable influence (in survival). Angina pectoris decubitus (an attack coming on while at rest in contrast with one during or immediately following effort) was found in 103 (20.6 per cent) of the 497 cases. There were no significant differences in the average duration of the disease to death or in the living between this group and that of the group as a whole. . . . "

The three men point out that it is not only helpful for the doctor to know something of the average life expectancy in general in angina pectoris but also "for the patient himself and for his family, rather than to leave merely the impression that prediction is impossible and that the Sword of Damoeles may fall at any moment. Such a state of affairs is for many persons so paralyzing that they are prone to sit for many years awaiting the end, unable to carry on a useful or happy life, or else, hardened by the thought, they may lead a reckless existence which can in truth hasten their end."

<sup>\*</sup> In Surgery, Gynecology and Obstetrics for November, 1937, Volume 65, pages 688-689, I published "Simplified Procedure for Thyroid Exposure." A search through standard textbooks on surgery and a review of recent surgical literature did not show this procedure. Later my attention was drawn to the article by Professor Enderien in Der Chirurg. Zeitschrift für alle Gebiete der Operativen Medisin for April 1, 1932, entitled "Zur Technik der Operation des Kropfes." The thyroid exposure outlined above is similar to that described by Dr. Enderlen.

# SUBASTRAGALOID DISLOCATIONS

With a Report of Two Cases of Dislocation of Subastragaloid Joint and Fracture of the Os Calcis, One of Which Was Compounded

MAURICE CULMER O'SHEA, M.D., New York City

SUBASTRAGALOID dislocations are an uncommon but not an unusual injury. Like many fractures about the ankle joint, they are the result of a sudden powerful impact exerted against the skeletal structure and its accom-

panying ligamentous supports.

A subastragaloid dislocation may be defined as a displacement of the osseous anatomy with its accompanying soft parts distal to the astragalus (talus). This dislocation is usually somewhat oblique and may be in any one of four directions. Medial displacements are most common, and lateral displacements are somewhat less common. Backward displacements are reported as occurring in several instances, but forward displacements are most unusual. However, no matter in what direction the main displacement is, it is usually at an oblique angle.

This fact was emphasized many years ago by Da Costa¹ but has been passed over in most descriptions of cases in the literature of the past decade. An examination of the illustrations of these reported cases will bear out the accuracy of this statement regarding the usual obliquity

of the displacement.

A subastragaloid dislocation must not be confused with a total dislocation of the astragalus (talus), for in this latter condition the astragalus (talus), is completely displaced from its articulations with the bones of the leg, as well as from its articulations with the bones of the foot. This latter condition will not be considered in the scope of this paper.

## Occurrence

In 1811, Judcy<sup>2</sup> reported the first cases of this condition, but it was not until 1853 that the condition was adequately described by Broca.<sup>2</sup> In 1858 Henke added further to the description and recognition of the condition.

Deetz' in 1904, collected 72 cases of this type of dislocation. Baumgartner and Huguier, in 1907, brought the total to 85 cases, while Schand, in 1939, added other cases, so that 139 cases were analyzed. Of these, 77 were of the medial type of displacement, 46 were lateral, 10 posterior, and 6 of the forward type. In all the cases reported in the literature, there is only one other

case that was compounded and had an accompanying fracture of the os calcis. That was one reported by Bolling in 1923, in which the dislocation was posterior. Baumgartner reported in the cases collected by him that the condition occurred nine times more frequently in men than in women, but subsequently Schand, in a larger series, found the incidence to be six times as great in males. Most cases are in persons between the ages of 20 and 30.

The most recent forward displacements were reported in 1906 and 1918, and the posterior displacements in 1907, 1908, and 1923. No cases have been reported in twenty years and in thirty-five years only two have been recorded in which the displacement was believed to be anterior or posterior. After reviewing some of these cases, it is this author's opinion that some or all of these should have had their oblique displacements described as either medial or lateral rather

than as forward or posterior.

Prior to 1925 only one case had been reported in the German Army in thirty years, and Trendel reported that it occurred in only one case in ten years at Bruns' Clinic, in Germany. Eliason's states that in a series of 528 cases of dislocation only 8 were at the subastragaloid joint. From the case records of Massachusetts General Hospital and his personal experience, Wilson's reports only 9 cases, 3 of which were from four to five months old.

#### Causes

In the past the most frequent causative factors of this type of injury have been direct blows on the side of the ankle, falls, and automobile accidents. However, it remains to be seen whether when the present war is terminated and an analysis is made of the injuries sustained by the military forces how frequently this condition will have occurred among the aviators and paratroops as a result of faulty landings after long and hasty descent in parachutes.

These injuries result from a severe torsion of the foot or a wrenching of the tarsus while a powerful impact is being exerted along the line of force of the limb. The foot is usually forcefully adducted or abducted while it is at a right angle to the leg, and the displacement occurs when the violent force is exerted along the long axis. Moore<sup>10</sup> states that to produce this lesion in a cadaver the ligament from the os

(From Med J. Sobotta: Atlas der deskriptiven Anatomie des Menschen, Munchen, J. F. Lehmanns Verlag, 1925.)

calcis to the astragalus had to be cut. If this was not done, fracture of the malleoli resulted. It is an alternative injury to adduction and abduction fractures of the ankle.

# Diagnosis

This injury is difficult to diagnose by manual or clinical evamination because shortly after it occurs there is tremendous ecchymosis, swelling, and tenderness. Later, extensive bleb formation may occur. X-rays usually are necessary to diagnose the condition accurately. If the patient is seen immediately after the accident and if the condition were to be diagnosed clinically. then reduction should not be delayed so as to confirm the diagnosis by roentgenograms.

# Pathology

The deformity resulting from this injury is vast and often gruesome. In cases of medial displacement of the foot, which are the most

frequent, the external malleolus protrudes and almost pierces the skin, while the limb itself resembles a tremendous clubfoot. The circulation of the limb sometimes is impaired, while extensive ecchymosis of the skin and marked soft tissue swelling is the rule rather than the exception When the foot is crushed or the astragalus is fractured or completely displaced, the delicate nutrient blood supply of the bone itself may be damaged, and since revascularization is slow, an aseptic necrosis of the body of the talus may result. Sneed11 points out that the blood supply to this bone is relatively poor and that a transcervical fracture not infrequently results in Shrock,12 nho quotes the research work of McKeever in 1939, demonstrates that the blood supply of the astragalus is from several minute nutrient vessels which are branches of the anterior tibial artery. One branch pierces and runs along in the astragaloscaphoid ligament. where it subdivides into four branches before

entering the bone on the supermedial aspect of the neck of the talus. There was no evidence that any blood vessels enter the bone from the ligaments on the posterior, anterior, and medial

aspects.

In subastragaloid dislocations the relation of the malleoli to the astragalus remains unaltered, and the mortise of the ankle joint, where some motion is still possible, is intact. The actual displacement occurs in the subastragaloid and astragaloscaphoid joints, where the distal foot, having been torn free of its ligamentous attachments, is displaced obliquely to the medial or lateral sides, sometimes slightly forward and sometimes posteriorly, depending on the nature and direction of the causative factor. The os calcis is twisted in the same direction as the foot and is not in its proper relation to the malleoli (Fig. 1).

The tendons of the digitorum longus and the tibialis posticus muscles are occasionally displaced from their grooves and interposed between the bones, making reduction difficult (Fig. 2).

The superficial cruciate ligament, which binds the dorsiflexors of the foot and toes to the other structures, is usually severely torn by the trauma, thereby permitting displacement of many tendons and at times even having its torn ends wedged in the luxated joint. When one considers the great strength, both individually and collectively, of the superficial cruciate ligament and the five deep ligaments of the joint, dislocation of it seems almost impossible. To accomplish a complete dislocation of the subastragaloid joint, the following deep ligaments must either be ruptured or torn free from their osseous attachments: the talo-

calcaneal ligament and the fibula calcaneal ligament of the lateral surface, the tibiocalcaneal and tibionavicular ligaments on the medial side, and the bifurcate ligament on the dorsal surface (Fig. 3).

The strong, long plantar ligament and the calcaneonavicular ligaments on the sole of the foot are not injured by this trauma and are held intact, thereby causing the os calcis to be displaced with the forward part of the foot.

## Complications

Fractures of the external malleolus, the articular surface of the tibia, the talus itself, and the

os calcis may occur as a result of the same force that caused the dislocation. Eliason<sup>8</sup> states that fractures of the external malleolus occurred in 50 per cent of his cases. Fractures of the astragalus have been reported by several investigators, but prior to the author's case only one other case of fracture of the os calcis was reported.

Compound injuries are not common, for in 1894 Dehoey<sup>13</sup> was able to compile a list of only 26 compound dislocations, and in 1942 Wise<sup>14</sup> added 3 more cases to the meager list. In the case herein reported the dislocation and fracture were compounded both from without by a larger wound and from within by a small puncture

wound over the malleolus. Skin necrosis may occur early in some of these cases unless they are adequately reduced. Laget<sup>15</sup> reported a case in which skin necrosis compounded the injury within four hours, while some other authors have disclosed that they found the skin in good condition when the dislocation had not been reduced in five or more weeks. Compounding occurs in about equal frequency whether the dislocation is lateral or internal and results from the skin's being too tightly stretched over the head of the astragalus and the malleoli.

Infections are a rarity among the more recently reported cases, although a decade or two ago this complication was more frequent and in the opinion of the surgeons usually necessitated an astragalectomy.

#### Treatment

This injury must be adequately treated and reduced at the earliest possible moment. Speed in reduction is even more important in this type of injury than in almost any other type of dislocation or fracture because of the rapidity with which necrosis of the skin frequently occurs in the tensely drawn skin stretched over the head of the astragalus, and because circulatory impairment is not uncommon. The reduction must be not alone for the dislocation but also for any fracture that might complicate the condition if a good and painless functional result is to be Complete reduction cannot be accomplished unless all the muscles are adequately relaxed by a general or spinal anesthetic. To assist in this relaxation of the muscular structures about the ankle, the knee joint should be fleved, thereby further relaxing the pull on the achilles tendon by the gastrocnemii muscles. With the knee fleved and the leg adequately fixed or held, traction should be exerted on the foot along the long axis of the limb for several minutes. Then an attempt should be made while traction is still being exerted, first, to increase the deformity slightly and then with counter pressure against the talus to manipulate the bones back into alignment. When reduction is accomplished, it is usually accompanied by a quite audible snapping sound. Immobilization in a plaster cast extending from the midthigh to the toes, keeping the knees lightly flexed and the foot at a right angle to the leg, should be maintained for eight weeks. If the displaced tendon of the posterior tibialis muscle prevents reduction, it may become necessary to divide it, or if some of the torn fragments of the cruciate ligaments should become interposed, an open operation may be necessary. Since the availability and efficacious value of the sulfonamides have been realized, frank infections seldom, if ever, occur and the resultant

astragalectomies previously advocated under such circumstances no longer have been necessary. In compound injuries adequate débridement and the generous use of sulfonamides in and about the wound are indicated.

Unless reduction is accomplished within the first few days after the occurrence of the dislocation then an open operation will usually be necessary to accomplish the purpose successfully. However, if several weeks should pass before reduction transpires then an arthrodesis of the subastragaloid joints will invariably be necessary if a painless, stable, weight-bearing pedal extremity is to be the lot of the afflicted person.

If early successful reduction is possible, the patient should be permitted to bear weight on the foot after the eight-to-ten-week period of immobilization in plaster. In the ensuing weeks of convalescence the proper use of physiother-apeutic measures will accelerate the absorption of the inflammatory reaction and reduce the edema in the neighboring tissues, thereby helping to increase the range of motion in the injured limb.

## Prognosis

Those cases that are reduced early and without instrumentation have an excellent prognosis for a good, useful, and painless joint for life. However, this prognosis becomes increasingly less favorable when there are complicating fractures, infections, and delayed reductions.

## Case Reports

Case 1.—Mrs K E, aged 33, a housewife, was admitted to St Vincent's Hospital at 4 25 a.m. on March 22, 1942 She gave a history of having been mjured while driving her automobile along the highway when she was crowded off the road and crashed into the steel-retaining walls of the roadway. She was pushing hard on the brake with her right foot, and as she crashed she felt something snap in her ankle. She suffered injuries to her right ankle, right elbow, and nose.

Physical Examination - There was a small horizontal laceration one-half inch below bridge of nose but no fractures. Right elbow: Several superficial abrasions of elbow area of the right elbow but no The right foot was displaced medially and the astragalus could be felt prominently under the skin of lateral aspect. The injury to the ankle was compounded both from within (puncture wound under lateral malleolus) and from without (laceration and abrasion) on the dorsal lateral aspect of foot. One laceration was transverse on the dorsal lateral surface of the foot and measured 11/4 inches in length. A second smaller laceration measuring 1/2 inch in length was located on the lateral aspect of the foot over the malleolus. There was an enormous swelling of foot and ankle, and a considerable amount of swelling was reduced by expressing several

Fig 4. X-rays showing oblique medial dislocation of the subastragaloid joint. Foot is displaced medially and slightly posteriorly. The fracture in the anterior-superior portion of the os calcis is visible.

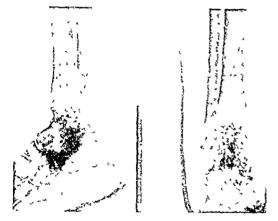

Fig. 5. Postoperative x-rays showing a complete reduction of the subastragaloid dislocation The fracture of the os calcis is visible

ounces of blood from the wound. The foot was adducted in a varus position and resembled a massive clubfoot.

X-Ray Examination.—X-rays of right foot show evidence of medial and posterior dislocation of the foot at the subastragaloid joint and fracture of the os calcis in its anterior superior portion (Fig. 4).

Laboratory Examination.—The urine, the blood count, and the Kahn test were normal.

Operation.—The diagnosis of compound fracture of the os calcis and compound medial dislocation of the subastragaloid joint having been made, an attempt at reduction of the fracture was made within two hours of the time of injury.

.Under cyclopropane, ether anesthesia, the skin

was scrubbed and cleaned, débridement of wound was performed, several ounces of blood were expressed from wounds, sulfanilamide powder was implanted in wound before suturing, and the surrounding skin was covered with same drug and with sterile dressings. Then when patient was deeply anesthetized the knee was fixed at an angle of 45 degrees, steady traction along the long axis of leg was made for five minutes, before manipulating the foot by temporarily slightly increasing the deformity and then with counter pressure over the lateral side of the astragalus manipulating the displaced bones into proper alignment. As the dislocation was reduced, a quite audible "snapping" sound could be heard in the operating room. Dorsiflexion of the foot was now possible. The foot and leg were immobilized in plaster-of-paris posterior and sugar-tong splints

Postoperative x-rays showed the dislocation to be reduced with the bones of the foot in their normal relationship. The fracture involving the anterior superior portion of the calcaneal bone showed slight separation of the fragments (Fig. 5).

The patient was returned to bed and the leg was elevated on two pillows. She received six doses of combined gas gangrene serum and tetanus antitoxin and was given adequate doses of sulfathiazole by mouth each day. During the following three days her temperature remained at about 100 F., and on the following postoperative day it was normal. At this point, contrary to the advice of the hospital staff, she signed the responsibility book and left for home in a neighboring state, where she placed herself under the care of a Dr. W. Here proports that the wounds healed cleanly, that he removed the cast on May 2, 1942, six weeks after the injury, that she regained good function and use of her foot about July 17, 1942; that pain and disability were not improved from May 2, 1942, to June 30, 1942, dur-

ing which time normal exercises and diathermy were given, that recovery of function was markedly accelerated by daily treatments of pulsating galvanic surge (B2), which was given from June 30, 1942, to July 17, 1942, at which time the patient was discharged in good condition

Follow-Up Examination on December 8, 1942.— The patient states she can walk normally and is free from pain except at certain changes in the weather Physical examination revealed that both wounds were well-healed and that there was no swelling present in ankle or foot. Motion in the foot was as follows: dorsiflexion, 10 degrees beyond a right angle, plantar flexion, normal; abduction, 10 degrees, adduction, 5 degrees; and inversion was limited to about 5 degrees It was our opinion that weight-bearing was allowed at a very early stage of her convalescence, considering the fact that she also had a fracture of the os calcis Follow-up x-ray of the right foot and ankle, on December 8, 1942, showed that the fracture involving the anterior superior margin of the os calcis was united and that there were moderately advanced arthritic changes at the opposing surfaces of the scaphoid and calcaneal bones (Fig. 6).

Case 2 -W. N, aged 56, a painter who was working on a twenty-foot-high scaffolding on October 10, 1943, when it toppled over, suffered marked mushrooming of the comminuted fractures in both of his calcaneal bones and a lateral-anterior dis-location of his right subastragaloid joint. The patient was not operated on immediately after the injury, as the doctor who first treated him failed to recognize the presence of the dislocation and simply immobilized both fractured os calces in plaster boots

Physical Examination —Patient was in mild shock after the accident. In the ensuing weeks the skin did not show any evidence of circulatory impairment as the lateral displacement was not marked, but there was considerable ecchymotic swelling of the whole of both tarsal and ankle areas

X-Ray —X-ray revealed the navicular (scaphoid) bone to have been dislocated dorsally and laterally and rested on the dorsal surface of the neck of the astragalus, which was displaced downwards was considerable communation of both os calces, with multiple fracture lines entering the astragalocalcaneal joint

Operation —An open reduction of the dislocation of the right astragalo-navicular joint and an arthrodesis of all the right subastragaloid joints were performed three weeks after the injury. At a subsequent operation the left subastraguloid joint was fused because of the comminution and displacement of the fragments of the os calcis. At the time of this writing the patient is still confined in St. Vincent's Hospital with both legs in plaster casts. He is free from pain, and postoperative v-ray reveals good position of bone fragments

## Conclusions

Subastragaloid dislocations are uncommon injuries which result from a severe impact to the foot while it is forcefully adducted or abducted

The great embarrassment and impairment of the circulation make early reduction under general anesthesia imperative. Delayed reduction may result in necrosis of the skin and comnounding of the lesion.

The limb should be immobilized in plaster from the thigh to the toes for from eight to ten weeks, following which time weight-bearing should be encouraged.

The prognosis for a painless, useful foot is good if reduction is accomplished early.

Two cases of subastragaloid dislocation complicated by accompanying fractures of the os calcis are reported.

# PUBLICATIONS TO USE METRIC SYSTEM

The A. M. A. has announced that future editions of New and Nonofficial Remedies, Useful Drugs, the Epitome of the U.S. Pharmacopoeia and National Formulary, and Interns' Manual (with the consent of the of the Council on Medical'Education and Hospitals), as well as other Council publications, will give quantities and dosages exclusively in the metric

This procedure is in harmony with the growing and current practice of prescribing vitamins, hormones, and sulfonamide preparations Council's concise historical presentation of the The units of measure formerly in common use empha-

sizes the value of adopting a uniform method of presenting quantities and dosages While daily by grains and barley corns, the kingly nose and regal thumb, and the combined length of the left feet of "sixteen men who lined up heel to toe as they left church on a Sunday morning," workers in the exact sciences appreciate the value of the simplicity, convenience, and precision of the metric system. Universal adoption of this system will be a manifestation of rationality and of interprofessional and international cooperation great practical utility.—J.A.M.A.

## NUTRITION OF THE INDUSTRIAL WORKER IN THE UNITED STATES AND ABROAD

Ross A. Gortner, Jr., Ph.D., Washington, D.C.

CINCE the entry of the United States into the present world conflict, more and more attention has been given to good nutrition as a means of improving the health, morale, and productivity of the civilian population. In this respect this country lagged behind Germany and Britain, who recognized early that the man in the factory or in the mine was as bound up in the future outcome of this conflict as the man in the trenches. The advent of mechanized warfare has made the success of an army more than ever dependent upon production on the home front.

Although it has long been held by nutritionists that a poor diet reflects itself in the health and well-being of workers, this aspect has not, until recently, received much attention from the workers or even from most industrial health officers. Little work has been done on the effect of nutrition on the productivity of industrial workers while on their jobs, but it has been observed that production is invariably highest right after meals, and workers who omit breakfast produce at a considerably lower level during the morning hours than do those who eat three meals.1 Other studies 2,3 have shown that supplemental rations of bananas or cod liver oil and milk given between meals markedly reduced absenteeism of women employees. Various other reports have stressed the importance of certain vitamins for offsetting fatigue 4,5 and partially protecting the worker against exposure to toxic chemicals.6

In 1916, at the request of President Wilson, the National Research Council was established under the National Academy of Sciences to serve as a quasi-official advisory body to all branches of the government, including the armed forces. In November of 1940 the Food and Nutrition Board of the Council established a Committee on Nutrition in Industry (now the Committee on the Nutrition of Industrial Workers) to study the diets of industrial workers and the prevalence of malnutrition in this group, about which little was known. Some of the problems facing this Committee were: (1) to make extensive surveys of the adequacy of the meals chosen by workers; (2) to determine the actual nutritional status of workers based on blood and urine analyses

and inspection for various pathologic changes; (3) to study the adequacy of feeding facilities in or around the many rapidly expanding or newly constructed war plants; (4) to investigate the desirability of allocating special rations of certain types of foods to workers performing very heavy manual labor, etc.; and (5) to ascertain the extent of loss or destruction of vitamins during the preparation of food in industrial food services.

Although much remains to be done, a good beginning has been made. In the summer of 1941, Dr. Robert S. Goodhart, vice-chairman of the Committee, visited more than 30 large industrial plants and inspected the lunches selected by the employees. He found that only 10 to 25 per cent of the workers chose milk and that the majority chose poorly balanced meals even when a good selection was available.

In an extensive study of the diets of 1,103 male workers in a large California aircraft factory, Wiehl observed that only 2 per cent of the diets were equal to or but slightly below the recommended amounts for five groups of foodsnamely, green or yellow vegetables, citrus fruits or tomatoes, milk, eggs, and lean meat or fish. More than half of the diets were far below the recommended amounts in two or more of these groups. In terms of specific nutrients, the following were most frequently inadequately obtained: ascorbic acid, riboflavin, calcium, vitamin A, and thiamine. The yardstick used in calculating these desired amounts was the Recommended Dietary Allowances adopted by the Food and Nutrition Board in May, 1941.8

The actual nutritional status of various population groups, as determined by clinical observation or analysis, is at present being actively investigated. Preliminary findings by Borsook9 on approximately a thousand aircraft workers in California showed that 42 per cent had low plasma ascorbic acid levels (less than 0.5 mg. per 100 cc.); 19 per cent showed signs of premature nerve degeneration, based on loss of sensitiveness of the toes to the vibrations of a C-256 tuning fork; 47 per cent showed conjunctival evidence of vitamin A deficiency (Bitot's spots); 28 per cent had hemoglobin levels below 14 Gm. per 100 cc.; and riboflavin deficiency, as evidenced by characteristic capillary invasion of the cornea, was almost universal.

A group of biochemists at Emory University in Atlanta is at present engaged in studying the

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 4, 1943. Associate Executive Secretary, Food and Nutrition Board, National Research Council, Washington, D.C.

nutritional status of hundreds of subjects based on vitamin analyses of blood and urine. Although their results are still too incomplete for accurate conclusions to be drawn, they have uncovered some interesting facts. A large percentage of the subjects examined fell below the accepted vitamin standards, and nearly all subjects who measured high in vitamins drank milk regularly. As might be expected, people in bad health showed up poorest, and professors and medical students, who knew what constituted a balanced diet, showed up the best. Approximately half of a group of draftees fell below the standard.

I have cited data indicating that a large proportion of the working population fail to receive an adequate (or optimum) diet. Are we justified in saying that a man may be malnourished when he shows no objective signs of specific nutritional deficiency? At a meeting of the Food and Nutrition Board of the National Research Council in New York City three weeks ago. Dr. Lydia Roberts gave an illuminating report on Puerto Rico, where she had recently spent six weeks studying the diets and nutritional status of the populus. Although she found the dietary habits and food situation to be very poor and the native population to be definitely malnourished, still there were very few obvious symptoms of deficiency of any specific nutrient. This confirms other observations that multiple dietary deficiencies usually inhibit the development of specific deficiency symptoms. Only recently Ivy and coworkers10 reported on the decreased work output of medical school students when transferred from a normal adequate diet to one which was deficient in B-complex vitamins. Although all subjects on the deficient diet for two months showed a marked decrease in work output as measured on a bicycle ergometer, at the same time there were no objective evidences of vitamin B deficiency other than lack of pep, anorexia, and the early development of leg pains during exercise. These are all symptoms which would normally pass unnoticed or be attributed to other causes.

What are the reasons for the apparently widespread incidence of malnutrition? They are somewhat different today from what they were a few years back. However, then as now, the main factors are primarily poor food habits, ignorance, poverty, and inefficiency in equitably distributing foods. The urban dwellers in the lower economic brackets are accordingly hardest hit, and it is largely from this population group that the industrial workers are drawn. When war came and industry began to mushroom, the demand for workers caused incomes to soar. This prosperity was reflected in a nearly 40 per cent increase over the past six years in money spent for food, and this has necessarily been accompanied by some improvement in the national diet.

However, this mushrooming of industry has presented a serious problem from the standpoint of providing adequate eating facilities for work-This problem was recognized by the National Nutrition Conference for Defense which was called by the President and held in Washington in May, 1941. At that time it was recommended that all contracts calling for the construction or expansion of defense plants should include provisions for facilities to feed adequately the employees. However, such facilities are today either inadequate or lacking in many plants. This is especially serious where many thousands of men migrate to a new plant in what was a sparsely settled area just a few months before. In such locations the eating places outside of the factory are usually wholly inadequate. Steps are being taken to counteract this situation.

The barrier of ignorance as to what constitutes a good diet is slowly being pushed aside. A widespread interest in nutrition has developed among the workers and their families, management, and communities. It has also extended to the industrial physician, who not so long ago too frequently felt that the diet and nutrition of workers did not fall within his scope. Now the American Association of Industrial Physicians has an active committee dealing with just this subject of nutrition in industry. Various concerns (Westinghouse, General Electric, and Servel are a few) have had remarkable success in stimulating community interest and enthusiasm by forming clubs, having regular meetings with demonstrations by dieticians, circulating pamphlets containing lists of attractive menus and other useful information. etc.

The Nutrition in Industry Division of the Nutrition and Food Conservation Branch, War Food Administration in Washington is actively concerned with promoting proper eating conditions and the serving of nutritious meals in industrial plants. In this capacity they have aided the establishment of effective programs of nutrition education for employees, have provided information on posters, pamphlets. news releases, programs, etc., and have suggested cafeteria and canteen menus which provide the worker with necessary foods compatible with food shortages, rationing, and reasonable cost.

Food as served is rarely nutritionally comparable to the fresh product. Losses in food value occur all along the line during storage, processing,

cooking, and serving. With respect to some factors, losses in the preparation of foods for mass feeding may be enormous. Recent assays11 of the thiamine, riboflavin, and ascorbic acid content of a "daily special" meal taken off the serving table during the regular meal period in a large industrial cafeteria in New York revealed that 92 per cent of the thiamine and 82 per cent of the ascorbic acid were lost during preparation. Much of this loss of nutrients is unnecessary and may be avoided by following a few simple rules such as (1) using fresh fruits and vegetables as soon as possible after delivery and keeping them cool and crisp prior to serving raw or cooking, (2) cooking such products quickly with little water and minimum exposure to light and air so that vitamin losses are not accentuated. (3) serving promptly without long periods of standing on steam tables or in warmers, and (4) using short cooking methods (sautéing or broiling) for meats or roasting at low temperatures.

So far I have said little about the nutritional situation of workers abroad. Britain has marked shortages of such protective foods as milk, eggs, and citrus fruits—all of which have been considered as "must" constituents in the American dietary. Nevertheless, the British seem to be getting along despite the fact that most of the population has dropped down 5 or 10 pounds to a rather stabilized "war weight."

Much credit is due the British system of food control<sup>12</sup> which has been successful in obtaining an adequate and even flow of foods into distribution channels and in distributing these equitably to all individuals and classes in the community.

The problem of whether special rations should be given to different groups of workers in Britain was widely debated, but it was finally decided that, because of the difficulty in classifying workers according to the nature of their work, all individuals should receive the same ration regardless of whether they performed light or heavy labor. Increased supplies of certain foods are, however, made available to canteens and restaurants which cater largely to industrial workers. Where the nature of the work is such that canteen facilities cannot be provided, special cheese allotments are granted. Children receive a smaller meat ration than adults, but the government has resorted to subsidies to make, among other things, milk, eggs, and oranges available to children. Cod liver oil and orange juice are supplied free to young children, and mothers and children are given priority for obtaining milk at a reduced price.

Various foodstuffs have been fortified, but this program has not gone so far as it has in this country. Margarine is fortified with vitamins A and D, while bread has added calcium. All bread is made from 85 per cent extraction flour.

An extensive program of communal feeding has been set up in the schools, factories, and mines which provide the workers with good mid-day meal facilities. Early in the war the Minister of Labor ordered that canteens be established in all plants employing more than 250 workers. It is hoped that these facilities will be retained after the war.

Finally, the Ministry of Food has been conducting a widespread educational campaign among consumers, stressing the nutritive value of foods and the needs of the body, and instructing housewives in the best methods of preparing foods.

A striking example of the effects of "nutritional conditioning" on building up health and physique is the result obtained by the British Army with would-be recruits. A group of more than 800 rejectees was given an optimum diet, plenty of sleep, hard physical work, and healthy recreation. As a result, 87 per cent of these men were later accepted by the army, while only 5 per cent were discharged on the grounds of medical defects.

In Canada, as in this country, the war has caused a shift in the population from rural areas and small towns into industrial centers. Although no actual studies have been made on Canadian workers as a group, much may be inferred regarding their nutritional status from several surveys14 which have been performed within recent years on urban populations. These showed that the workers' diets were markedly deficient in the protective foods, foods which supply the needed vitamins and minerals. Deficiencies were noted in vitamins C, A, and the B vitamins; calcium and iron were frequently far too low; even the protein and calorie intakes were insufficient in some instances. The new industrial boom has in some respects changed the eating habits in a detrimental way. Many workers rush off with little or no breakfast to plants where it is difficult, if not impossible, to get an adequate lunch. The overall picture is analogous to what we have in the United States.

A year and a half ago the Department of Pensions and National Health in Ottawa established a new branch called Nutrition Services to attack the problem of malnutrition among the whole population and especially among war workers. It is the function of Nutrition Services to: (1) see that war plants get adequate food facilities; (2) make available expert opinions and nutritional information to other branches of the government; (3) sponsor and advise on research pointed toward informing and protecting the people; (4) generally aid the public to

improve nutrition in the home by advising through propaganda leaflets, speakers, etc., on the production, purchase, and preparation of foods. Much credit is due Canada, and Dr. L. B. Pett, in particular, for the rapid strides that have been made in improving nutrition in industry in that country.

In conclusion, the nutritional status of industrial workers in this country is, at present, far from satisfactory, but the problem is being actively attacked and progress is being made. Information which is being accumulated on the incidence and causes of malnutrition is aiding in the formulation of steps for combatting this condition. The people are becoming conscious of their diet, industries are becoming aware of the importance of having their employees nutritionally fit, and the government is putting its shoulder to the wheel to enable and encourage industry to adequately feed its workers in these days of rationing and priorities. The nutritional progress which is being made during this period of national emergency should not only materially aid the war effort but it should also play an even larger role in establishing and maintaining a lasting peace.\*

# SCIENTIFIC BASIS FOR THE RECOMMENDED DIETARY ALLOWANCES

LYDIA J. ROBERTS, PH.D., Chicago

EARLY in 1941 the Food and Nutrition Board of the National Research Council set forth a table of recommended allowances for the various dietary essentials (see Table 1). These allowances were accepted by the National Nutrition Conference which assembled in Washington in May of that year, and since that time they have been universally used in nutrition programs throughout the country. They have also been adopted in Canada and to some extent, at least, in England. The purpose of this paper is to outline briefly how the values were arrived at and the scientific basis for the levels used.

Soon after its formation, the Board realized the need for such standards, both for the guidance of those responsible for feeding the armed forces, and for workers engaged in nutrition work with the civilian population. It is true that numerous standards had been set up by individual workers or groups, but these varied widely in completeness and in the amounts of a given dietary essential recommended. For example, estimates for requirements of vitamin A ranged from 1,000 to 10,000 I. U.; for ascorbic acid from 30 to 120 mg.; for thiamine from 0.75 to 3 or 4 mg., and similarly

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 4, 1943. From the University of Chicago, Chicago, Illinois.

widely for other nutrients. It was realized that requirements cannot be definitely established until much more experimental work is carried out, but it seemed desirable to survey the evidence and to derive a table of allowances that would represent, so far as possible, the combined judgment of nutrition authorities and thus be more widely accepted and used. A committee of the Board was appointed to undertake this

The procedure consisted of two major steps. First, the published evidence on the requirements for the different factors was critically examined and appraised. In addition, requests were sent to a large number of nutrition authorities, particularly those doing research in this field, for their judgments as to the requirements for any factors for which they had any experimental or other basis for a decision. From the evidence thus assembled, tentative allowances were set up. These were then submitted to all contributors, as well as to all members of the Board, for criticism. On the basis of the replies the allowances were reformulated, resubmitted to contributors, again revised, and after discussion and final revision by the Board, adopted in their present form. The values as accepted. therefore, represent the consensus of more than

50 nutrition authorities as to the best allowances to use until ones derived from more experimental evidence can be obtained. It was understood that they would be revised from time to time as more knowledge on any of the factors becomes available. That time has now arrived, and after three years of use, a thorough rechecking of evidence with the view to consequent revision is now being undertaken by the Committee.

## Accepted Values

It is not possible within the limits of space available to review fully the scientific evidence on which each of the allowances is based for all ages and conditions, but some of the considerations that led to the choice of values will be briefly outlined.

Calories.—The caloric allowances for adults are the usually accepted ones for the traditional "average" man and woman of 70 and 60 Kg., respectively, and for moderate levels of activity. The values for children are based on a compilation of all energy studies in the literature1 and on a preliminary analysis of unpublished studies of

several hundred children made by Roberts and Blair. There will be some adjustments in these values when more detailed analysis is made of the data, but used with judgment they are reasonable as they now stand.

The calories required will at all age levels vary above or below these allowances in the proportion that the individual varies from the average in size and activity. Recognition of this fact is especially important in adolescence where the variation in size and activity is the greatest. Thus a small, relatively inactive boy of 15 years may need only 3,000 calories, while a large, very active one of the same age may require 5,000 calories or more. Fortunately, in the case of calories, the appetite usually takes care of an increased need if adequate food is available, and if there is a deficit, it is reflected in a loss of weight or failure to gain. Tables of caloric requirements are useful chiefly in planning food allowances for institution groups or for families under care of welfare agencies. Even here they should be used only as rough guides. For individual children the best guide to the calorie needs is the amount the appetite demands,

providing the adequacy of intake is indicated by normal growth and sufficient amounts of fat and muscle "padding."

Protein.-The protein allowances for adults are based on the standard of "one gram per kilogram," advocated by Sherman,2 which is widely accepted and used as one that provides a reasonable margin of safety. The higher allowances for pregnancy and lactation are supported by the work of Macy and Hunscher,3 et al., Coons.4 and others, who have shown that growth of the fetus and adnexa in pregnancy and the demands for milk production in lactation markedly increase the protein needs. This increase begins in the latter half of pregnancy and is greatest in lactation when milk production is at its height. The quantities given in the table are indicative of the relative needs, rather than accurate requirements, for these vary greatly with the size of the individual.

The allowances for children are derived from an unpublished compilation of balance studies on children of all ages, as found in the literature. These indicate that protein intakes per kilogram on which good positive balances have been obtained decrease from about 4 to 3.5 Gm. in infancy; 3.0 to 2.5 in early childhood; and to 2.0 to 1.5 in late childhood and adolescence to the adult standard of 1.0 Gm. The total amounts given in the table represent approximately these values. They also provide for about 15 per cent of the total calories from protein. actual amounts required will vary with the size of the individual and also with the quality of the protein. An infant fed on breast milk, for example, thrives on a protein intake much lower than the standard here given, apparently because of the superior quality of human milk proteins. It is probable that the allowances given are considerably above actual requirements and represent rather amounts which it is desirable to supply, and which, moreover, can be readily attained in dietaries which provide adequate amounts of other nutrients. In planning practical diets, provision should be made for some of the protein to come from animal sources, in order to insure adequate intake of all essential amino acids.

Calcium.—The calcium allowance for adults was increased somewhat above the widely used Sherman standard of 0.67 Gm. per day.<sup>5</sup> Two lines of evidence suggested the need for this increase. The first is that supplied by Leitch.<sup>6</sup> By a series of calculations on metabolic data from the literature, she concluded that 0.55 Gm. might be considered about the maintenance level since at this intake equilibrium was attained in half of the studies analyzed. Allowing a 50 per cent increase above this for safety would give a

standard of 0.83 Gm. The second line of evidence is found in the work of Steggarda and Mitchell, and Outhouse et al., at the University of Illinois. These workers found that 10 out of 13 adult subjects were in equilibrium on 9 to 10 mg. of calcium per kilogram, while the remaining a required somewhat more. Using the 10-mg. value, the total for a 70-Kg. man would be 0.70 Gm. It is obvious that the standard should be somewhat above this. The allowance was therefore tentatively set at 0.80 Gm. for the 70-Kg. man, a value close to the one derived from Leitch's data.

The standards for women were set at the same level as for men, in spite of their smaller average size, in order to insure ample stores in preparation for the possible drains of maternity. The allowances for pregnancy and lactation are much higher in order to provide for the growth of the fetus and for the large amounts needed for milk production. These increased needs are indicated by the work of Macy et al., Coons, and others. As in the case of protein the precise values given may not be justified, but they are correct in indicating the need for greatly increased intakes of calcium during these periods.

Although numerous calcium balance studies have been carried out on children, only a few have been done from the standpoint of determining the requirement, and these have dealt largely with the preschool age. In arriving at the calcium allowances, special consideration was given to the more recent studies of Daniels¹ and of Outhouse et al.,¹¹o on preschool children, and of Wang¹¹ on adolescent girls. The earlier studies of Sherman and Hawley,¹² Wang et al.,¹³ were also evaluated, as were likewise the calculations made by Leitch⁶ as to the probable requirements during the period of growth.

In the study by Outhouse on 10 preschool children the stores of the subjects were first saturated by feeding a high amount of a calcium salt, and then the level adjusted downward to determine the lowest intake that would insure maximum retention. Three levels were tried. 370, 615, and 880 mg. The results showed that 615 mg. was definitely better than 370 mg. and as good as the higher amount and might therefore be termed the requirement of a preschool This is a little more than the amount contained in a pint of milk. This result is in accord, moreover, with those of Daniels and of Wang and with Sherman's early findings on 2 preschool children. It appears, therefore, that this amount is sufficient provided the stores are saturated, and the diet is otherwise adequate. In view of the uncertainty of these points always being assured, it seemed desirable to allow a margin of safety, and the allowance was set at 1 Gm.

50 nutrition authorities as to the best allowances to use until ones derived from more experimental evidence can be obtained. It was understood that they would be revised from time to time as more knowledge on any of the factors becomes available. That time has now arrived, and after three years of use, a thorough rechecking of evidence with the view to consequent revision is now being undertaken by the Committee.

## Accepted Values

It is not possible within the limits of space available to review fully the scientific evidence on which each of the allowances is based for all ages and conditions, but some of the considerations that led to the choice of values will be briefly outlined.

Calories.—The caloric allowances for adults are the usually accepted ones for the traditional "average" man and woman of 70 and 60 Kg., respectively, and for moderate levels of activity. The values for children are based on a compilation of all energy studies in the literature and on a preliminary analysis of unpublished studies of

several hundred children made by Roberts and Blair. There will be some adjustments in these values when more detailed analysis is made of the data, but used with judgment they are reasonable as they now stand.

The calories required will at all age levels vary above or below these allowances in the proportion that the individual varies from the average in size and activity. Recognition of this fact is especially important in adolescence where the variation in size and activity is the greatest Thus a small, relatively inactive boy of 15 years may need only 3,000 calories, while a large, very active one of the same age may require 5,000 calories or more. Fortunately, in the case of calories, the appetite usually takes care of an increased need if adequate food is available, and if there is a deficit, it is reflected in a loss of weight or failure to gain. Tables of caloric requirements are useful chiefly in planning food allowances for institution groups or for families under care of welfare agencies. Even here they should be used only as rough guides. For individual children the best guide to the calorie needs is the amount the appetite demands,

providing the adequacy of intake is indicated by normal growth and sufficient amounts of fat and muscle "padding."

Protein.—The protein allowances for adults are based on the standard of "one gram per kilogram," advocated by Sherman,2 which is widely accepted and used as one that provides a reasonable margin of safety. The higher allowances for pregnancy and lactation are supported by the work of Macy and Hunscher,3 et al., Coons,4 and others, who have shown that growth of the fetus and adnexa in pregnancy and the demands for milk production in lactation markedly increase the protein needs. This increase begins in the latter half of pregnancy and is greatest in lactation when milk production is at its height. The quantities given in the table are indicative of the relative needs, rather than accurate requirements, for these vary greatly with the size of the individual.

The allowances for children are derived from an unpublished compilation of balance studies on children of all ages, as found in the literature. These indicate that protein intakes per kilogram on which good positive balances have been obtained decrease from about 4 to 3.5 Gm. in infancy; 3.0 to 2.5 in early childhood; and to 2.0 to 1.5 in late childhood and adolescence to the adult standard of 1.0 Gm. The total amounts given in the table represent approximately these values. They also provide for about 15 per cent of the total calories from protein. actual amounts required will vary with the size of the individual and also with the quality of the protein. An infant fed on breast milk, for example, thrives on a protein intake much lower than the standard here given, apparently because of the superior quality of human milk proteins. It is probable that the allowances given are considerably above actual requirements and represent rather amounts which it is desirable to supply, and which, moreover, can be readily attained in dietaries which provide adequate amounts of other nutrients. In planning practical diets, provision should be made for some of the protein to come from animal sources, in order to insure adequate intake of all essential amino acids.

Calcium.—The calcium allowance for adults was increased somewhat above the widely used Sherman standard of 0.67 Gm. per day.<sup>5</sup> Two lines of evidence suggested the need for this increase. The first is that supplied by Leitch.<sup>6</sup> By a series of calculations on metabolic data from the literature, she concluded that 0.55 Gm. might be considered about the maintenance level since at this intake equilibrium was attained in half of the studies analyzed. Allowing a 50 per cent increase above this for safety would give a

standard of 0.83 Gm. The second line of evidence is found in the work of Steggarda and Mitchell,7 and Outhouse et al.,8 at the University of Illinois. These workers found that 10 out of 13 adult subjects were in equilibrium on 9 to 10 mg. of calcium per kilogram, while the remaining 3 required somewhat more. Using the 10-mg. value, the total for a 70-Kg. man would be 0.70 Gm. It is obvious that the standard should be somewhat above this. The allowance was therefore tentatively set at 0.80 Gm. for the 70-Kg. man, a value close to the one derived from Leitch's data.

The standards for women were set at the same level as for men, in spite of their smaller average size, in order to insure ample stores in preparation for the possible drains of maternity. The allowances for pregnancy and lactation are much higher in order to provide for the growth of the fetus and for the large amounts needed for milk production. These increased needs are indicated by the work of Macy et al., Coons, and others. As in the case of protein the precise values given may not be justified, but they are correct in indicating the need for greatly increased intakes of calcium during these periods.

Although numerous calcium balance studies have been carried out on children, only a few have been done from the standpoint of determining the requirement, and these have dealt largely with the preschool age. In arriving at the calcium allowances, special consideration was given to the more recent studies of Daniels¹ and of Outhouse et al.,¹¹o on preschool children, and of Wang¹¹ on adolescent girls. The earlier studies of Sherman and Hawley,¹² Wang et al.,¹³ were also evaluated, as were likewise the calculations made by Leitch6 as to the probable requirements during the period of growth.

In the study by Outhouse on 10 preschool children the stores of the subjects were first saturated by feeding a high amount of a calcium salt, and then the level adjusted downward to determine the lowest intake that would insure maximum retention. Three levels were tried. 370, 615, and 880 mg. The results showed that 615 mg. was definitely better than 370 mg. and as good as the higher amount and might therefore be termed the requirement of a preschool This is a little more than the amount contained in a pint of milk. This result is in accord, moreover, with those of Daniels and of Wang and with Sherman's early findings on 2 preschool children. It appears, therefore, that this amount is sufficient provided the stores are saturated, and the diet is otherwise adequate. In view of the uncertainty of these points always being assured, it seemed desirable to allow a margin of safety, and the allowance was set at 1 Gm.

This can be provided by a pint and a half of milk plus the rest of the diet. Beyond the preschool period the data on which to base requirements are very meager, and the allowances proposed are largely derived from the calculations of Leitch, and from balanced studies of Wang for adolescent girls, and Sherman's one 12-year-old These indicate that the calcium needs increase through the growth period to well above the 1 Gm. level and then decline to that of the adult. With these three points tolerably well indicated by experimental evidence—the preschool child, the adolescent girl, and the adultthe values for other ages were interpolated to correspond to the curve of normal growth. It is evident that the calcium needs of children is still a fertile field for research.

Phosphorus.—No special allowances were formulated for phosphorus, as there are few data on which to base them. It is safe to say that the phosphorus allowances should be at least equal to and probably somewhat greater than those for calcium. In general, moreover, it may be assumed that if the calcium and protein needs are met, the phosphorus requirement will also be covered, because the foods richest in these are also the best sources of phosphorus.

Iron.—The iron allowance for adults was set at the 12-mg. standard arrived at by Sherman<sup>2</sup> on the basis of balance experiments. The mean intake required for equilibrium in his subjects was 8 mg., and this was increased by 50 per cent to provide a margin of safety. Recent work by McCance and Widdowson, 15 Hahn, 16 and others indicates that the actual iron requirement, especially of adult males, is much lower than this. According to their evidence, iron is absorbed only in response to a need, as in growth or after blood loss, and there is practically no re-excretion of iron into the intestinal tract. That is, what iron the body gets, it keeps to use over and over again. If this is true, then iron will be needed and absorbed during the period of growth, and in women during the period of reproductive life. Once fully grown, the male would have no further need for iron, and the same would be true of women after the menopause. If this theory is accepted, then the adult man's requirement would be zero, or only a few milligrams, and that for the woman only enough to replace menstrual losses. Actually Leverton 17 showed that adult women could maintain balance on about 7 mg. of iron per day. In a later study,18 however, she found that a higher level was needed unless the diet was well fortified with all other dietary essentials. It is seen then that the allowances set are not in accord with the most recent evidence, some of which has been published since they were formulated. After due consideration

by the Board and other contributors, it was decided that, since the theory was relatively new and not all workers were as yet convinced of its practical applicability, and since the 12-mg. standard in use was one that could be easily obtained in otherwise good diets, it would be well to hold to this level until further definite proof of actual needs is forthcoming. The allowance for women was set at the same value as for men. In view of their smaller average size this provides for their relatively greater needs due to losses in menstruation.

The demands of pregnancy are estimated by Sherman to require an increase of about 3 mg. over the normal requirement. This amount was therefore added to the 12 mg, making an allowance of 15 mg. Moreover, McCance and Widdowson found good hemoglobil levels in pregnant women on this intake. Al though there is no evidence that the iron need are increased in lactation—since milk is very low in this mineral—it seemed wise to err of the side of generosity and keep the same allowance during lactation as for pregnancy.

Studies of iron requirement of children have been reported only for infancy and the preschool vears. Both Jeans and Stearns, 20 and Oldham and Schultz<sup>22</sup> showed that in infants 0.5 mg. per kilogram is near the minimum needed to maintain a positive balance and good hemoglobin level. From a critical appraisal of the results of Rose,21 Leichsenring and Flor,23 Ascham,24 Daniels,25 and Porter26 on preschool children it seemed that the need at this level could be met by 0.30 to 0.40 mg. per Kg. Using these values together with the average weights for these years, and allowing some margin of safety, the values for preschool years were obtained. For the child of early school age (7 to 11 years), the allowances are supported by the work of Johnston,27 who found that children of these ages could maintain normal hemoglobin levels on 0.35 mg. per Kg., or a daily intake of 9 to 10 mg. of iron, and that larger amounts gave no improvement. No data are available for the requirements of adolescence. The allowances were set empirically on the assumption that the needs would be actually greater than those of the adult during these years and that increases of the order used would probably be justified.

It is clear from the foregoing that the question of iron requirement is one that will receive special attention in the forthcoming revision. In the meantime, the fact that these allowances may be higher than necessary need give no concern since they will be readily attained in diets providing ample calories and other dietary constituents.

Vitamin A .- There is greater divergence in

the judgments of authorities as to the amount of vitamin A required than for any other dietary essential. Estimates for the same age may range all the way from 1,000 to 10,000 I. U. This situation is explained by these facts: (1) that there is not as yet any generally accepted method for determining the requirement; (2) that the amount needed varies as to whether the source is the vitamin itself or its precursor carotene; and (3) that the capacity of the body for storage of this vitamin complicates the problem. Most of the estimations of requirements found in the literature are based on studies of the amount needed to maintain normal dark adaptation in the subjects studied.

The allowance of 5,000 I. U. for adults was based largely on the studies of Booher,<sup>25</sup> Blanchard,<sup>29</sup> and Guilbert,<sup>30</sup> and the critical evaluation of the literature by With. These studies indicated that the requirement is 25 to 55 I. U. per Kg., which amounts to 2,000 to 4,000 I. U. per day, and twice or more than these levels if the source is carotene. Since approximately two-thirds of the vitamin A value in the average diet is contributed by carotene, it was decided that 5,000 I. U. would represent a fair overall allowance. The allowances for pregnancy and lactation were arbitrarily raised above these by amounts estimated to take care of added needs during these periods.

Since few studies have been made on children which throw light on this problem, the allowances had to be set on the basis of the judgment of the referees, plus some calculations on the per kilogram need. The amounts recommended are well above those actually found in the studies made. Lewis and Haig31 found that infants had normal dark adaptation on 18 to 20 I. U. per Kg. or total intakes of 135 to 200 I. U., and workers with older children have found intakes much below the allowances adequate. It is generally agreed that vitamin A requirement is related to body weight rather than to energy expenditure. If we accept Booher's highest per kilogram estimate of the need, and compute the requirements for children on this basis, the values for boys would be 550 I. U. at one year; 1,000 at 4; 1,430 at 8; 2,200 at 12; and 3,300 at 16 years. If, however, we assume that the requirements are relatively higher on the basis of weight, as in the case of protein and the minerals, and multiply these values by appropriate factors—for example, those for protein, as 3, 2.5, 2.0, 1.5—values about equal to those in the table are obtained. There is, however, no valid justification for this procedure, save that it serves in a measure to rationalize the values which the referees empirically decided they were willing to accept. It seems probable to the writer that the allowances are well above the actual needs. It seemed desirable, however, to keep them so in view of the lack of universal acceptance of the dark adaptation test as an entirely satisfactory method for determining requirement. Moreover, vitamin A, well in excess of the amounts given as standards, is readily obtained in diets containing desirable amounts of milk, eggs, and green vegetables. The quart of milk alone, which is commonly taken by one year, provides the 1,500 I. U. allowance without counting that from other sources, and the addition of other foods in later years brings it well up to the standards set

Thiamine.—The thiamine allowances were influenced largely by the comprehensive experiment of Williams, Mason, Wilder, and Smith<sup>32</sup> on the effect of induced thiamine deficiency in human subjects, and the step-wise return to normal levels. When the subjects were put on depletion diets, the urinary excretions of thiamine fell very low, and subjective and objective symptoms developed. When they were given graded doses of thiamine, it was noted that the excretions increased, and the symptoms disappeared when the intake approached the 1-mg. level. However, when 2 mg. were given, the subjects continued to improve and were in an optional state of well-being. This study seemed to indicate that at least 1 mg. was needed and that 2 mg. were more than enough since a marked rise in urinary excretion occurred on this intake. It seemed reasonable, therefore, to allow a 25 per cent margin of safety above the 1 mg., making a daily allowance of 1.25 mg. amounted to 0.5 to 0.6 mg. per 1,000 calories for the subjects studied. This value is reasonably in accord with the findings of: (1) Melnick and Field<sup>33</sup> who reported that 1 mg. was sufficient to maintain saturation in the adults; (2) of Wang and Yudkin34 who found good excretions at 1.35-mg. intake: and (3) with the estimate of Hughes<sup>35</sup> from his work on pigs, that an average man of 70 Kg. would require about 1.5 mg. (or 0.5 mg. per 1,000 calories). From these studies it was concluded that about 0.5 mg. per 1,000 calories would be a reasonable allowance. and the values for adults at varying calorie needs were calculated on this basis.

The studies by Knott et al., 36 constituted the main evidence for the needs of children. From studies on normal infants she found that intakes of 240 to 420 micrograms were needed for normal excretion. From studies on preschool children 37 she concluded that the need at this age was approximately 900 micrograms. This is in good agreement with the findings of Rose and Robb<sup>55</sup> that the intakes of healthy

preschool children range from 564 to 910 micrograms. When the standards in these three studies are computed on basis of calories, they are found to be in line with the 0.5 mg. per 1,000 calories arrived at for adults. Since this value seemed applicable to these ages—adults, infants, and preschool children—it was assumed that they might also be suitable for other ages, and the values given in the table were so derived.

Riboflavin.—There were but two experiments that could be utilized in setting the riboflavin allowance—one by Sebrell et al.,39 the other by Parsons40 and coworkers. Both groups of workers concluded that the requirement of the adult is approximately 3 mg. The conclusion in each case was based on the level of intake at which depleted subjects could return to normal, as judged by the urinary excretion. In the former study, the disappearance of cheilosis was also used as a criterion. Both groups found that at 2 mg. intake the excretion did not equal that on the control diet, while at 5 mg. it rose sharply. They deduced, therefore, that the requirement lay at about the midpoint between the two, or 3 mg. In appraising the data, however, the committee believed that they might be interpreted to indicate that 2 mg. or a little more might be fully as satisfactory. Evidence to this effect was, moreover, submitted by a number of referees. Another consideration was the relationship which had been shown in experimental animals between the thiamine and the riboflavin requirement. According to Elvehjem this is about 2 to 3, and other laboratory workers agreed that it is about of this order. The allowances for thiamine having been arrived at, riboflavin values were therefore derived by increasing the thiamine ones by 50 per cent. Since the values so obtained for adults corresponded fairly well with those the committee arrived at from the experimental evidence, they were accepted as the best estimates that could be made in the light of the meager evidence available.

There have been many suggestions that the riboflavin figures are too high, and there is some experimental evidence to indicate that this is the case. This factor will therefore receive special attention in the next revision.

Nicotinic Acid.—There were no human experiments on which to base the requirement for nicotinic acid. This is true because (1) difficulties in conducting balance studies have been encountered; (2) because blood changes in nicotinic acid are not very significant; and (3) because only a few values for nicotinic acid in foods were then available. The tentative standards were therefore derived largely by calcula-

tion from the nicotinic acid requirement of dogs, as found by Elvehjem, and the values checked against diets known to be adequate for prevention of pellagra in human beings. When the allowances were thus calculated for the different ages, it was found that they were approximately ten times the thiamine allowances. This observation gave further support to the validity of the values, for since both thiamine and nicotinic acid, as well as riboflavin, play a part in the oxidation-reduction system of the body through which the energy of foods is released, they might be expected to bear a fairly constant relation to each other.

Ascorbic Acid.—There is better evidence for the requirements for ascorbic acid for different ages and conditions than for any of the other vitamins. This is true because methods for determining the needs are better developed and accepted than for the others and more studies have therefore been made. Among the studies which were used in deriving the allowances were those of Hauck et al.,41 Todhunter,42 Fincke,43 for adults; Roberts44 for children of 8 to 12 years; Hathaway<sup>45</sup> for preschool years; Bessey and King46 and others for infants. In these and other studies, both the blood level of ascorbic acid and the urinary excretion test have been used as evidences of adequate stores, and an attempt has been made to find the lowest level of intake that will keep the body in a normal state of saturation as judged by these criteria. The chief points of argument have been as to what constitutes normal blood level, and what urinary excretion response to a test dose indicates saturation.

There is debate also as to whether complete saturation is necessary for normal health.

From the published reports of these and other workers, compromise allowances were set up for the different ages and categories, then submitted to the referees for criticism, and then revised. Fortunately, it was also possible at the meeting of the Institute of Nutrition to get together all of the workers listed above for a discussion and modification of the allowances.

The ones given in the table are the final ones so derived. They are understood to represent levels well above the minimum needed to protect against scurvy but below the amount needed for complete saturation. They are, in short, good allowances to aim at in common practice. Moreover, they are not difficult to attain or exceed in good dietary practice.

It is seen from the foregoing review that the actual experimental evidence for human requirements for the various dietary essentials is far from adequate and especially so for vitamin A and the B vitamins. Moreover, even though the need may be fairly well established for a given age or condition, there is rarely a complete series of studies covering the growth period, and data for adolescence especially are lacking. It is clear then that the allowances had to be set up partly on the basis of the judgment of nutrition workers whose experience gave them some basis for deciding what values to interpolate for those that were lacking. That the allowances so derived are reasonably satisfactory is attested by their use during the past three years. already indicated, there are indications that some of the values may be unnecessarily high, especially those for riboflavin and vitamin A, and for most values for pregnancy and lactation, and the new evidence for these will be carefully considered in the contemplated revision. However, it is believed that as they now stand they are good "allowances," if used as goals to aim at in dietary practice rather than as absolute requirements.

It is obvious that continued research is needed on all aspects of this important problem.

#### Discussion

Dr. Edward S. Rogers, Albany-There is much food for thought in the two papers by Dr. Roberts and Dr. Gortner and the large problems of investigation and practical application which they represent.

As Dr. Roberts has clearly shown, there are elements of empiricism still prevalent in our socalled dietary standards. While none of us, it seems to me, can seriously quarrel with the manner in which these standards have been tentatively set by the National Research Council, we must realize that at many points they are uncertain.

The methods of measurement and the interpretation of results as they relate to studies of balance with many of the vitamins lack the precision or understanding that are available-for example, in determining protein requirements on the basis balance, The National Research nitrogen Council and all investigators, of course, realize this and have carefully planned for it by the practice of adding a 25 to 50 per cent "margin of safety" to their calculations of need.

Such a procedure, however, in terms of a wartime food economy has interesting implications. This mark-up of food requirements, made in good faith at the conference table and in the laboratories of our scientific groups, can conceivably have an effect of amazing magnitude in terms of bushels or carloads or tons of food to be consumed.

On this scale, every percentage, every fraction of a percentage, that we raise our standards above their true (but as yet unknown) levels might act as an important force in the maldistribution of our already overtaxed food resources.

To err in the other direction, however, would be equally if not more serious in terms of our national and international food planning, national health, and the vigor with which we are able to prosecute the war.

Clearly, the position of the National Research Council is an unenviable one but none the less tremendously important. We who are at the functional level must give them all possible support, especially in the urgent problem of a more precise understanding of food requirements.

In our experiences with the problem of feeding the war worker, we feel that we are safely beyond the realm of the foregoing controversy—but on the wrong side! I mean that our estimates and studies of the dietary of our war workers in over fifty New York State war plants have convinced us that these dietaries are seriously below even the most conservative estimates of adequate standards.

I am among those who are convinced that the adequacy of the food intake in calories, in organic and mineral constituents, and vitamins bears a

direct and appreciable relationship to the worker's health and ability to produce.

We have proceeded along the lines of the national program and set as our goal the provision of one-third (or better, one-half) of the daily requirements for the worker at his on-the-job meal, where we know what he gets.

We are convinced, on the basis of dietary analysis and also of laboratory analysis of foods as consumed, that it is practically impossible to reach, to say nothing of exceeding, this objective in the majority of busy war plants, even when we have had the advantage of opportunities to use reinforced foods (using brewers' yeast especially).

Theoretically, this should not be so, but in practice, where reality must be faced, it is so. All the more reason, of course, for intensifying our efforts by education of worker and manager, by regulations as may be required, by study and improvement of methods, and by "reinforcement" when possible.

I should like, in concluding, to go back to the problem of precision in standards as it may relate to another important medical problem. I have

reference to the recently published studies of Foster and her associates\* on so-called "hypo-immunity" in relation to thiamine intake. In these studies (which have not, to my knowledge, been confirmed, but most certainly should be as rapidly as possible) it appeared that an excess of thiamine or a depletion of thiamine in the diet resulted in a sharp increase in the susceptibility to paralytic poliomyelitis of experimentally inoculated mice.

Presumably the mechanism of this occurrence at these two extremes is different, representing preponderant influences on host resistance on the one hand and virus virulence on the other.

With our growing positive approach to human nutrition, with our tendency to disturb, by aggressive action, the ratios and balances between the various nutritive elements consumed, it seems that there may also come serious responsibilities in in the understanding and discharge of which we shall need, more than ever, the precise knowledge of standards of which I have already spoken.

#### NEW YORK RED CROSS REPORTS ON YEAR'S WORK

The extensive war and home-front activities of the New York Chapter of the American Red Cross in the year ended June 30—reflected in the fact that more than 40,000 volunteers gave 5,000,000 hours of service—are summarized in the organization's eighty-page annual report made public in November.

Emphasizing that work for the armed forces was responsible for a tremendous increase in activities of the chapter's twenty-nine services, Maj. Gen. Robert C. Davis, executive director, said home service handled 121,393 cases as compared with 39,343 the preceding year. Home service assists in the problems of service men and their families.

Home service helps service men to obtain leaves, gives extended care to their families and handles inquiries concerning prisoners and men reported missing. To facilitate service, teletype machines were installed in the telegram department, which works twenty-four hours a day. Among the 371 volunteers in this service were doctors forming the psychiatric clinic.

Pride was manifest in that portion of the report dealing with the chapter's blood-donor service. It registered 364,861 volunteer donors and collected 257,303 pints of blood, winning a white star to add to its Army-Navy "E" flag for high achievement. The service, now at Fifth Avenue and East Thirty-seventh Street, was established in February, 1941, as the first blood-donor project to provide dry plasma for United States forces.

The financial report, submitted by Mrs. Mabel C. Langer, director of accounting, shows a total income of \$1,938,291.09, including a net share of \$1,880,624 from the 1943 war fund campaign. Expenses, including \$39,651 for administration of the blood-donor service, totaled \$1,235,070.27. This left a balance of \$703,220.

In his own section of the report General Davis stressed the new features of service added to the chapter's customary activities, which, he said, produced "an unprecedented record of service to the armed forces, to overseas war victims and to the community."

Innovations included a new volunteer service, the dietitian's aid corps, to assist in hospitals. The chapter also detailed Gray Ladies, motor corps and nurse's aids to assist at Halloran General Hospital, the Army Hospital on Staten Island. Many volunteers were assigned to the war prisoners' foodpackaging center in Manhattan, where the output rose to 13,000 packages a day by June.

Recruiting of nurses for the armed forces also was intensified during the year, the report shows. Between July 1, 1942, and June 30, 1943, the chapter recruited 1,625 nurses for the Army and Navy Nurse Corps.

Production service made 11,000,000 surgical dressings for the forces, filled 168,000 comfort kits for American troops going overseas and 60,000 convalescent kits for sick and wounded men being returned to this country, and made 43,500 garments for overseas war sufferers.

The canteen corps and motor corps were credited with rendering many services to the forces, for which reading matter was provided by the library and magazine service. Christmas service sent gifts to 5,000 hospitalized veterans and nurses from New York and Bronx counties.

Among the other services, first aid service issued 70,000 certificates and organized 100 first-nid detachments, while home nursing service taught 11,000 women to care for the ill. The disaster relief service, which stands ready to aid victims of enemy action, gave assistance to persons left homeless by a large apartment house fire.

#### PROBLEMS IN EARLY TREATMENT OF POLIOMYELITIS

JESSIE WRIGHT, M.D., Pittsburgh, Pennsylvania

IN THE past two years, as a result of publicity 1 through the Bulletin of the Allegheny County Medical Society and the Pennsylvania State Medical Journal, patients have been referred earlier for confirmation of diagnosis of poliomyelitis and immediate treatment, in some instances before paralysis had appeared. As a result, physical measures were started earlier than was possible when we did not see patients until after paralysis had been present for several days. When seen in the prodromal stage, signs of irritation of anterior horn cells were reflected clinically, at first by fibrillation of groups of fibers in case of mild insult, or by spasm of whole groups of muscles when inflammation in the cord was more extensive. At this stage, spasm of the posterior muscles of the body did not predominate, but rather agonists and antagonists were affected in much the same way. Three such patients were admitted to hospital with histories of gastrointestinal disturbances, sore throats, moderate fever, and soreness of muscles. No decrease in reflexes or individual muscle impairment was found, other than a certain reluctance to move the involved parts. Within twenty-four hours examination showed nuchal rigidity and tenderness along the spine and certain muscles of involved extremities. Spinal fluid findings were suggestive of poliomyelitis, and spasm of certain groups became marked, with inhibition of other groups, which, in many instances, were antagonists. Soon after the onset of poliomyelitis one cannot be sure which groups are inhibited by spasm of antagonists and which ones have true paralysis. These facts make no difference in procedures of treatment, since the spasm must be completely relieved and tendencies to contractures must be prevented or overcome before the inhibited or weakened groups can be analyzed with accuracy for tentative classification.

It has been interesting to watch the groups of patients from the last two seasonal outbreaks through the different stages of early convalescence. We noticed that certain patients seen during the prodromal stage of the disease had fibrillation and spasm of muscles, some of which had an early return of function, others became inhibited and gradually recovered, while still others became inhibited, continued to give no response, and were characterized finally by typical flaccid weakness. This suggests that the initial reactions to the irritation of the virus and

its toxins were fibrillation and spasm, and that further activity of the virus led to destruction of the motor cell, followed by disintegration of its axis cylinder and paralysis of one hundred or more muscle fibers associated with it. Other muscles that had been characterized by fibrillation and spasm returned to normal after a few days of fomentations, suggesting that their neuromuscular units had been irritated but not severely damaged. In such instances fomentations were started immediately after diagnosis. It seems logical to suppose that if the congestion in the cord and associated structures and the stasis in muscles which are in spasm are relieved by improvement of circulation through favorable postural position and early physical therapy, regression of inflammation is encouraged so that one may hope to limit the number of cells permanently damaged by the virus and save surrounding cells from impairment or destruction due to altered nutrition and metabolism.

Neurologic examination of many acute inflammations, irritations, or insults to the central nervous system and its coverings shows varying degrees of spasm in the posterior neck, in the back, and in the hamstring muscles. These signs have been recognized for many years. The idea that spasm was present in other muscles of involved parts in poliomyelitis was original with Sister Elizabeth Kenny. Since it is impossible to make direct observations of cords in living human beings with acute poliomyelitis, one must depend on results of animal experimentation, clinical observation, and results of treatment to explain physical signs. After the keeping of a careful record of signs and changes during onset, during the acute stage of the disease, and during convalescence, certain postulations may be made and offered for confirmation or question in future research. Early spasm may be caused partly by initial irritation from infection and inflammation, partly by reflex splinting to avoid painful movement, and partly by muscular tension generated by the patient's reaction to pain.

Most reports in the past few years are in favor of beginning treatment immediately after diagnosis. Sister Kenny's method is being followed more or less, in many medical centers, for treating acute and early convalescent poliomyelitis. Fomentations, proprioceptive stimulation, and synchronous movement taking advantage of reciprocal action have been described too often in the past months to need repetition here.

A question has arisen as to whether other

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 4, 1943.

vo

forms of heat would not be as effective as fomentations in the acute stage for sedation, decongestion, and relaxation of spasm. Dry heat stimulates sensory nerve endings, while moist heat decreases sensory afferent impressions reaching the central nervous system, and gradually cools, giving a vasomotor tonic effect. In our experience moist heat gives quicker relief from pain and spasm than dry heat.

As spasm and tenderness disappear, physiologic movement followed by rhythmic contraction and relaxation of muscles gives further relief of congestion locally and systemically. As pain and spasm diminish, the muscles and the patient relax so that metabolic products which have been locked in rigid muscles are mobilized by an improved cycle of circulatory interchange. Thus we find reasonable explanations for the changes brought about by these physical measures.

I am not in accord with the idea that individual muscular re-education should be discarded. Perhaps use of only one phase of two opposing movements has been overdone in past years. But we have had some experiences with reciprocal movement which make us vary the technic when necessary. In most instances, use of both phases of reciprocal action is satisfactory, even when one muscle is stronger than its inhibited antagonist. However, certain exceptions have come to our attention. In the group of patients from 1941, one child, who had made almost a complete recovery, was ready to go home at the end of six months. The quadriceps was the only muscle which had not given any indication of power. After several lessons, the mother did not grasp the idea of rhythmic movement of the knee by the Kenny method. I asked the instructor to turn the child on her side and try knee extension according to the Lovett method. The quadriceps gave a definite contraction, strong enough to completely extend the knee, with guidance, in the horizontal plane. The patient continued the exercise in the side-lying position until several weeks later a fair grade had been reached. Then the instructor tested her in the back-lying position, encouraging reciprocal action, and the response was satisfactory in both phases of knee movement. Similar variations have been used in other patients when indicated.

A grant from the National Foundation for Infantile Paralysis has made it possible to add special instruction in our regular physical therapy course, and also to take small groups of graduate students, with adequate background, for individual instruction in early treatment of poliomyelitis. I have been interested in the preconceived ideas that these students have when they come. In the past six months the special students were asked to express their idea of the

effect of the Kenny method when treatment was started at onset. Most of them replied that all muscles could be returned to normal and no deformities would occur. Although recent papers by a number of physicians have stated clearly that early physical treatment may limit the residual weakness to the units permanently damaged by the virus, but not prevent paralysis, there is still a widespread misconception about what can be accomplished. It may be possible to prevent deformities while the patient is under close supervision during the early stages of the disease. But if residual paralysis persists, contractures and distortions may occur. Four out of 30 patients in our 1941 group required modified brace support on legs to limit tendencies to deformity. One patient had to have the calves stretched gently in plaster casts. One had division of an iliotibial band to improve function. So far this year (1942), in a group of 15 patients, 2 have needed help in the form of light casts, which are worn at night and removed in the daytime. Certainly, when treatment is started immedi-

Certainly, when treatment is started immediately after diagnosis and continued under close supervision, the affected parts are of better tone, show less atrophy, have better neuromuscular and joint function, and are used more naturally than in patients who, during previous years, were immobilized or greatly restricted during acute and convalescent stages. A review of certain case histories from the last seasonal outbreak of poliomyelitis may be interesting and instructive. Variations in individual response to treatment will be described.

Case Reports

Case 1.—H. S. was a boy of 6 years who came to Children's Hospital critically ill. The throat and nasopharynx were filled with mucus, respiration was abdominal and irregular. The boy could not swallow, was unconscious, with his eyes partly glazed over with a dried web, and the trunk in a marked degree of opisthotonos. His arms and legs were in a flexed position and could not be straightened even with gentle, steady movement. The boy had received such a severe insult to his nervous system that analysis of the extremities was not attempted. The mucus was cleared from his nasopharynx with an electric aspirator and fomentations were started immediately on his neck and trunk and changed every half hour during all twenty-four hours. They were tried on his legs, but he became restless and the fomentations were removed from the legs. When his throat was aspirated, the sound seemed to irritate him and we noticed that he moved his arms and legs, although he did not straighten them completely. The gag reflex was absent. In a few hours the neck and back muscles relaxed enough that the body and head could be flat on the bed. The binder, which held the trunk fomentation in place, was kept tight over the abdomen and loose over the chest. In this way it was possible to encourage thoracic breathing. Respiration remained irregular for twenty-four hours. Nourishment was given by vein during the first three days, at the end of which time the child aroused enough to notice what went on in his room. Fomentations were added to the legs and changed every two hours of the daytime twelve hours. Neck and trunk fomentations were continued day and night and changed every two hours. Less mucus was accumulating in the throat and it was noticed that the gag reflex had returned and the patient attempted to swallow. Feeding by teaspoon was tried carefully, and by the end of the fourth day the boy could swallow orange juice and other liquids given in this fashion.

By the end of the first week breathing was regular but still shallow. The boy could take a soft diet, and analysis of the extremities could be made with a fair degree of accuracy. Some spasm was still present in the posterior neck, back, hamstrings, calves, the right pectorals, right elbow flexors, wrist extensors, and upper trapezius. No sensory impairment was found. The chief muscles inhibited were the anterior neck muscles, the abdominals, quadriceps, dorsal flexors of the feet, the right deltoid, the right triceps, and wrist flexors. The boy now tolerated the fomentations on the legs and so the right arm was included, besides the neck, back, chest, and abdomen, which had been packed day and night since his admission to the hospital. By the end of two weeks only slight spasm of the groups mentioned remained, and weakness became evident in the right deltoid, elbow flexors, wrist flexors, and abdominals. Although individual muscle weakness

was noticed, no group was completely paralyzed. Physiologic movements were used on affected extremities, and the patient was instructed in correct breathing, relaxing the neck, expanding the chest, and retracting the abdominal muscles. The middle of the third week of quarantine I went in to see him one morning and found him trying to climb over the side of the bed. At this stage his legs were essentially normal, but there was still individual weakness of the right deltoid and elbow flexors. The boy breathed and swallowed normally, he was able to take a general diet, and his bladder and bowel function were normal. On account of the severe initial illness his family was instructed in allowing only gradual increase in his activity, arranging frequent short periods of sitting in good posture during the first week at home, which was the fourth week of the disease, permitting momentary standing the fifth week, taking his pulse before and after each activity. Instructions were given in maintaining normal range of motion in the spine, legs, and right elbow, in addition to special exercises for the right deltoid, elbow flexors, and for correct breathing. I saw the boy at my office six weeks after the onset of his illness, and be was able to walk and use all parts of the body normally, except the right arm, the deltoid of which was fair, and the elbow flexors almost good. His family restrained him with difficulty from running and being overactive. He has been seen since then, and improvement of the right arm continues.

I call attention to the fact that although the fomentations were obviously of great importance in relief of initial symptoms, the boy would not have lived if he had not had excellent nursing care to keep the throat clear from mucus, to prevent hypostatic congestion, and to see that proper nourishment was given and wastes eliminated. I believe that seeing that the patient has a generous fluid intake, proper nourishment, normal bowel evacuation, and variation of position to prevent hypostatic congestion, are essential parts of effective early treatment.

Case 2.—Another patient, F. G., a 3-year-old girl, seen while paralysis was still spreading, has provided clinical instruction during the early course of the disease. Her family doctor was called one morning in September because she could not stand on her left leg. By the time he reached the patient's home she could stand, walk, and run as usual. She had no fever, sore throat, headache, gastrointestinal disturbance, muscular pain, or soreness; there was no change in reflexes, and no tenderness was found. He reassured the family and asked them to call him if any further unusual manifestations occurred. That evening they called to tell the physician that the other leg had given out and the child could not stand at all. Again he examined her very carefully and found some diminution of patellar and Achilles reflexes, but no muscular tenderness or elevation of temperature. She was put to bed. The next day the temperature rose to 100° and the child complained of discomfort in the back and lower legs The physician found leg reflexes further diminished, abdominal distention, tenderness and spasm in the back and hamstring muscles without sensory impairment, and weakness of the left leg. The patient was sent to Municipal Hospital with a clinical diagnosis of poliomyelitis. Spinal fluid findings confirmed the clinical impression. Fomentations were applied to the neck, back, and legs, and changed every half hour. By the evening of the second day of the illness some weakness was present in the left arm, and nuchal rigidity became apparent. Fomentations were added to these areas and changed every two hours. The next morning the other arm was affected, nuchal rigidity was more marked, breathing was shallow but regular, and we wondered if the illness was going to be of Landry's type. However paralysis stopped at this point and no further areas were involved. Fomentations, even when used day and night, did not give as quick relief from pain as usually occurs. The child had third degree or marked spasm in the neck, back, left gluteus maximus, left hamstrings, right quadriceps, and both calves, with inhibition of anterior neck muscles, left quadriceps, and dorsal flexors of both feet. In a few days, as the tenderness subsided and spasm decreased, range of motion in all joints became freer. In the arms there was marked spasm of the right pectorals and right upper trapezius, and moderate spasm of the elbow flexors. The left arm seemed to be generally inhibited. Fomentations were stopped at night because of excessive sweating

attended by rapid pulse and moderate prostration. At the end of the first week the child appeared toxic and acutely ill. Probably part of the sweating was due to toxemia. In spite of limitation of the packs sudamina developed, and it was necessary to apply the packs only every other two hours, using cephalic cold and allowing the body to dry between applications. In spite of this, excessive perspiration continued, with resultant tendency to maceration of the skin so that the fomentations were discontinued entirely except for the ones on the neck and trunk. Fortunately, by this time the most severe tenderness had disappeared, muscle spasm had diminished, and the child was more comfortable.

We found on investigation that the child had the same type of constitution and poor vasomotor tone as the mother and had a tendency to perspire excessively, even in cold weather. We believed that this accounted, to a large degree, for the reaction that the child had to the fomentations. The skin had cleared by the end of the third week in quarantine, and when she was released from isolation moderately hot fomentations were tried for thirty minutes out of each two hours, and were followed by cold sponging of the body to improve vasomotor The skin was kept dry for one hour out of two. After two weeks of alternate hot and cold in this manner, she was able to tolerate fomentations given in the usual way for twelve hours daily, changed every two hours.

The child had poor eating habits, and probably before this illness her tissue tone had suffered as a On a well-balanced diet, rich in vitamins, all of her responses and her behavior began to improve so that she could tolerate fomentations followed by physiologic movements in the same way as the average infantile paralysis patient. When she was in Municipal Hospital, a neurologist, who was a friend of the family, felt that she had a most severe paralysis of all body parts. By the end of November, three months after onset, she had reached the point where she had normal range of motion in all joints, normal power in the arms and trunk, good return in the hips and knees, and the ankle and foot muscles all showed some response and were improving. Now she is walking without assistance and without a limp, with the help of high shoes.

I review the occurrences in the course of this patient's illness to show that fomentations can and must be varied, and to bring out the fact that reasons may be found for undesirable reactions to fomentations. In this case excessive sweating may have been caused by severe toxemia, poor vasomotor system, and improper nourishment, upon which foundation the moist heat exaggerated an inherent tendency to sweat. Intravenous dextrose in physiologic salt solution has been helpful in limiting excessive perspiration in some of these patients.

Although the case reports I have given describe unusual situations, we did see other patients who had the usual type of onset and course of the disease. However, in 1942 there were fewer new cases than usual in our section of the country and many of them had atypical onsets.

We know from gross and microscopic findings in poliomyelitis that the inflammatory reaction from activity of the virus results in congestion. swelling, engorgement of vessels, and effusion of fluid and blood, so that the cord, membranes, and structures in the intervertebral foramina are enlarged and crowded in severe attacks of the disease. Besides invasion and destruction of anterior horn lower motor cells by the virus and its toxins, obviously the prolongation of a state of congestion with stasis of circulation and ischemia of surrounding cells would lead to altered metabolism of other neurons, possibly with permanent insult in addition to the primary effect of virus on the cells in the center of the inflammatory zone.

Dr. Temple Fay has remarked about lack of appreciation of the degree of intraspinal venous and perineural congestion accompanying many infections, irritations, and injuries affecting the structures within the spinal canal. He has spoken of opening the canal for various purposes and seeing degrees of congestion that could cause damage in addition to primary disease or other insult.

Hansson, 1 Schwartz, 2 and Weiss 3 have made careful studies of action currents in poliomyelitic muscle.8 Such contributions will clarify the interpretation of hyper- and hypoactive responses and furnish ground for further explanation of effect of early treatment. Unquestionably Sister Kenny<sup>4</sup> has made an invaluable contribution to the treatment of acute poliomyelitis and has modified the conception of the peripheral manifestations of the disease. But we must not lose sight of the importance of treating the patient as a whole, as well as considering all problems of the disease. Nutrition, psychotherapy, physiologic positions of advantage in bed and later when upright, as well as scientific records of signs and progress are all important. Available and timehonored forms of treatment may still prove uscful in meeting certain needs in various stages of the disease. We shall continue to use to advantage the Silver\*method of preventing stasis of circulation by special postural measures in bed, the Lovett†-Merrills method of muscle testing, the Kendalle percentage grading, the Lowman underwater re-education, and light, efficient supports when indicated. No method of treatment. however efficient, will prevent the disease and its aftermath.

We look forward to the day when poliomyelitis will be controlled largely at its source, and effective immunity will be within reach. In the meantime, recent advances in early treatment will

<sup>\*</sup> David Silver, M.D., professor emeritus of orthopaedic surgery, University of Pittsburgh School of Medicine, † Robert Lovett, M.D., late professor emeritus of orthopaedic surgery, Harvard University School of Medicine.

help to limit paralysis and favor earlier return of function.

#### Discussion

Dr. K. G. Hansson, New York City-It is of great interest to me to listen to a paper like Dr. Wright's. We have had a great deal of confusion during the last two years about poliomyelitis, and it is only of late that we can see the orderly outline of a new aftertreatment. Two years ago I wrote a paper dividing the after-treatment of polio into three parts-the acute stage, the convalescent stage, and the chronic stage. I see no reason, two years afterward, to change what I said then. It is a pleasure to me to see other doctors coming to the same conclusion.

I agree with Dr. Wright that Sister Kenny has given us a valuable contribution in the acute stage, the early recognition of spasm, and the intensive treatment of this spasm by means of hot fomentations. In addition to what Dr. Wright brings out about moist heat. I would emphasize the fact that the maximum heat is at the beginning and the heat gradually diminishes, thereby allowing a partial constriction of the capillaries. It also follows that this form of heat application is safer in every way. The proprioceptive stimulation and the synchronous movements are valuable additions to our muscle re-education. Dr. Wright did not speak of muscle testing. I use this as the only rational estimation of the progress of the patient. I can't believe that a muscle test once a month interferes with the muscles in a child.

I believe with Dr. Wright that individual muscle re-education should not be discarded in the convalescent stage. Cases of residual paralysis will undoubtedly follow the same pathologic-physiologic laws which they always have followed.

There has been a dangerous tendency in the last two years to turn over the care of polio patients to pediatricians and epidemiologists who have never had previous experience with polio treatment. Dr. Wright brings out the importance of this point in discussing two cases. I am certain she could have added many more. I should like to add two of my own experience:

Case 1.-A boy, 12 years old, spent four months in a respirator in spite of recent reports that the iron lung was unnecessary. Every time he was taken out of the respirator, he stopped breathing.

We had to use oxygen therapy with his packs and muscle re-education.

Case 2 .- I have heard of a polio patient with fever being packed until his temperature rose to 108 F. and the patient passed out. We must use common sense even if we try out new methods.

In the chronic stage, our concept of polio has not changed; braces and other supports as well as orthopaedic operations are just as necessary as before.

I would ask Dr. Wright to describe the Silver

method in more detail. I would also ask Dr. Wright to give us some idea

of the end result of her polio cases in Pittsburgh. I want to thank Dr. Wright for a very frank and rational paper on her experience with poliomyelitis.

Dr. Francis J. Gustina, Buffalo-Dr. Wright has properly brought out many of the well-known As she noted facts in regard to this infection. one must treat entirely on a symptomatic basis. It is therefore necessary to treat symptoms and the patient, not the disease. The earlier this begins the more comfortable the patient will be, and the more likely will better results be obtained. cannot look into the spinal cord and see how marked has been the process of inflammation, nor can we hazard a prediction on the basis of physical findings as to whether paralysis will ultimately result. Certainly, as she suggests, it does seem probable that regression of cord inflammation may be encouraged by measures designed to relieve the symptoms and signs of muscle spasm.

Her explanation of the possible reasons for the success of early physical measures is in keeping with observed changes, and makes for a better understanding of the need for early treatment. Certainly each case must be individualized. Any standard method must be varied to meet different conditions. Measures which have been found to be valuable in former times should not be hastily discarded for newer innovations.

Unfortunately, in the minds of many the introduction of the Kenny treatment has seemed to envision a future of infantile paralysis without any residual impairment of muscle function.

This concept must be eradicated. A number of cases will continue to show residual paralysis, and still require orthopaedic measures for their proper management. Early institution of physical procedures will certainly give a better outlook for freedom from deformity, but constant follow-up will still be needed to avoid contractures and distortions.

The case illustrations bring out clearly the need for good nursing care and medical judgment in special instances. Surely we cannot neglect the patient and concentrate only on his illness. Little things sometimes give big results.

In the present state of our knowledge concerning this disease, it would seem the better plan to give all patients the early benefits of physical measures, even though a number of them would probably not require them. Until we know how to find out what is actually happening in the spinal cord, and find some specific treatment to overcome these effects, our reliance must continue to be on symptomatic treatment, according to the plan which has so far given the best end results.

It has been a pleasure to discuss Dr. Wright's paper, and I want to congratulate her on the fair attitude she has taken in regard to the role of physical therapy in treating this disease. Her open mind on the various problems involved and her insistence on a rational appraisal of all factors and measures should do much to help clear away many of the misconceptions regarding this disease and its most effective treatment.

Dr. Wright-In regard to Dr. Hansson's question about muscle testing, I may say that we find distinct advantage in keeping records. Muscle spasm and inhibition, in the acute stage, are analyzed as much as possible from inspection and palpation without disturbing the patient or moving involved parts. After the acute stage we keep the same type of muscle charts we have used through the years. I do not believe anyone can remember from month to month or from year to year what state of the muscles existed early in the disease. If we do not keep accurate records, we may be misled in final conclusions about how much recovery has taken place.

Twenty years ago Dr. David Silver called attention to the importance of the prone position in preventing stasis of the circulation in the posterior trunk, including the region of the spinal cord. In those days it was not unusual to see patients who had been lying on the back for days or weeks in splints, with almost no turning except at the time of morning care. Parts were so tender and patients experienced so much pain that all those in attendance were reluctant to turn them, or feared change of position lest inflammation would be spread and the acute stage prolonged. Dr. Silver advocated

turning the patient as one unit, not allowing segmental movement, at reasonable intervals, usually every two hours, supporting all parts of the body in physiologic positions of advantage. We still use this postural program with certain variations to suit the need of each patient.

Dr. Hansson asked about results of treatment when physical therapy was started at the onset of the disease. Pain is relieved more quickly; spasm, tenderness, and limitation of motion diminish more rapidly than when treatment is deferred; and the tone of skin, subcutaneous tissue, and muscle is better. The patient's psychologic reaction is favorable under minimum restriction, a feeling of comfort and well-being, and relatively rapid transition in treatment and condition of affected parts. After the acute stage, the problems are much the same as they have been always, and are met by wellknown measures. Unless no neuromuscular units have been permanently damaged, gradual resumption of daily routine brings the old problems of balance between rest and activity, tendency to atrophy of affected muscles, and overdevelopment of unaffected parts. Some patients, who manage without bracing, under close supervision, eventually need support to help prevent deformity or to improve function. Contractures and deformities still develop and need orthopaedic care.

Dr. Gustina has emphasized quite correctly the fact that physical treatment is only part of early treatment of poliomyelitis. The care given by the pediatrician, the resident, and nursing staffs fortifies the patient and makes possible treatment of the motor impairment.

I appreciate the discussion of my paper by Dr. Hansson and Dr. Gustina and the comments made by Dr. Syracuse.

#### 163.400 CANCER VICTIMS IN 1942

Cancer took 163,400 lives in the United States last year, 3,474 more than in 1941, ranking second only to heart diseases as the principal cause of death. The Census Bureau reported in November that the rate of deaths from all causes, however, fell to 10.4 per 1,000 persons, lowest on record, reflecting sharp reductions in the rates for pneumonia and influenza and for automobile accidents.

The bureau released the following statistical report on 1942 cancer deaths by age groups and sex:

Female Male Age Total 35 214 323 763 4,935 30,959  $\frac{42}{182}$ Under 1 year 77 396 1-4 years 5-14 years 15-24 years 25-55 years 56-64 years 272 549 10,015 595 1.252 36,604 37,739 65 years and over Unknown 708 56 77,933 85.467 163,400 Total

#### A.C.F. TO PUBLISH YEAR BOOK SUPPLEMENT

The subject of publication of a complete Year Book of the American College of Surgeons in January of 1944 was discussed at a meeting of the administrative board with the chairman of the board of regents. It was the consensus, because of the many Fellows of the College who are in military service and into whose hands it would not be possible to place the directory correction form, that publication of a complete Year Book would be undesirable at this time, since facts pertaining to many of the Fellows have changed materially since the Year Book was published in January of 1942.

The administrative board recommended to the board of regents that in lieu of a complete Year Book at this time there be published a Supplement for 1948, this supplement to contain geographical and alphabetical listing of Initiates, 1943, and an over-all alphabetical list of all present Fellows of the College admitted through 1943. . . . —Bulletin, American College of Surgeons

# A SECOND REPORT ON ROCKY MOUNTAIN SPOTTED FEVER IN NEW YORK STATE EXCLUSIVE OF NEW YORK CITY\*

E. R. Maillard, M.D., and E. L. Hazen, Ph.D., New York City

THE prevalence of Rocky Mountain spotted fever in one county on Long Island was reported in 1935¹ and the results of agglutination tests with Proteus X 19 and blood serums from ten patients with clinical and epidemiologic evidence of spotted fever were also presented. Since then, serologic studies² have been made on blood serums from twenty-six additional residents of Long Island believed to have Rocky Mountain spotted fever.

The largest number of cases studied in any year was eight, in 1939. According to Parker,<sup>3</sup> the incidence of spotted fever is influenced markedly by meteorologic factors that affect the tick population. Gordon<sup>4</sup> has also pointed out that the extent of the tick population, the percentage of infected ticks, and the human population, or the extent of migration into the area, are influencing factors.

In so far as can be determined from the records of the State Department of Health, Long Island is the only known focus of Rocky Mountain spotted fever in the State. Other foci may be disclosed as a result of increased migration into thinly populated rural areas, as in the Adirondack Mountains, where extensive mining operations and related projects are now in progress. The need for recognition of the disease and knowledge of methods of diagnosis is obvious.

Some of the criteria considered important by experienced investigators<sup>3,5,6,7,8</sup> for the differentiation of spotted fever from endemic typhus fever, the disease with which spotted fever is most commonly confused, will be mentioned here.

In spotted fever the rash becomes more generalized, usually appearing first on the extremities and extending to the palms and soles, which in endemic typhus are not involved. A definite history of tick bite is of distinct value in differentiation, since spotted fever, not endemic typhus, is transmitted by the tick. Biopsy of skin lesions may often serve to establish a differential diagnosis, since in typhus the rickettsiae are found in the endothelial cells lining the blood vessels while in spotted fever the microorganisms are found not only in the endothelial cells but in the smooth muscle cells of the arteri-

oles. Of the laboratory tests used, the Weil-Felix test with the O strains of Proteus X is the most practical and is of distinct aid in diagnosis. The serums from spotted fever cases may agglutinate OX 19, OX 2, and OX Kingsbury, while Spencer and Maxcy<sup>9</sup> and Davis<sup>10</sup> report that serums from endemic typhus fever in this country agglutinate only OX 19. Our findings have been in accord with those of Parker,<sup>6</sup> who observed that in the majority of cases of spotted fever the Proteus OX 19 strain is agglutinated in much higher titer than OX 2, but that in occasional cases the OX 2 titer is definitely higher.

This report presents a serologic study of blood specimens from twenty-six patients believed to have had Rocky Mountain spotted fever, with a summary of the clinical and epidemiologic findings. The results of the histologic examination of specimens of skin, heart, spleen, and liver removed at autopsy from one of the patients, together with the gross anatomic findings, are also discussed.

#### History and Epidemiology

The patients lived in rural districts of Long Island. The disease was contracted during the spring, summer, and fall, when outdoor activities were greatest. Twenty-four had a history of tick bite or contact with ticks, or had been working or camping in places where exposure to ticks was unavoidable. Two persons without a definite history of contact or exposure to ticks lived in sections where for many years spotted fever has occurred. One was a boy, aged twelve, and the other a governess, who during her fatal illness was never sufficiently coherent to answer questions. None of the cases could be associated with flea bites. The ages of the patients ranged from 7 to 73, and the majority were males.

The illnesses began usually from two to ten days following the history of contact with ticks, the onset being acute, with chills, fever, headache, general malaise, stiffness and pain in back of neck. and restlessness. No characteristic lesion was observed at the site of the attachment of the tick. and not infrequently the site of the bite could not be found. In the more severe infections, the patients showed drowsiness, stupor, and, at times, delirium. A red macular eruption appeared variously, between the second to the seventh day of illness, later becoming petechial in character; in some patients the lesions coalesced to form hemorrhagic blotches. The rash appeared usually on the extremities, later involving other parts of the body. In the majority of instances the infections were mild; a few were severe. One was complicated by diabetes mellitus and another with pneu-

<sup>\*</sup> The agglutinative titers of the serums represent reactions of not less than 3+; "marked agglutination" as herein used signifies a reaction of 4 or 3+ in a dilution of 1:160 or higher of the serum, and "partial agglutination" signifies a reaction of 4 or 3+ in a dilution of 1:80 or less of the serum.

The symptoms observed in this group corresponded to those of Rocky Mountain spotted fever described by Rumreich<sup>8</sup> and Parker<sup>6</sup>. Six of the patients died.

#### Histology

One of the more severe infections terminated fatally on the fourteenth day of illness.

This patient (J. J.) was a 20-year-old woman. The gross anatomic findings at autopsy were a macular erythematous eruption of the skin with confluent hemorrhagic areas. The spleen was enlarged, fairly soft, and weighed 200 Gm. The stomach was markedly dilated and showed submucous petechiae. The lungs were congested and edematous with scattered areas of consolidation in the lower lobes. Tissue from the skin, heart muscle, liver, and kidney was studied microscopically and showed foci of perivascular infiltration by inflammatory cells, including mononuclear, plasma, and mast cells, and also scattered lymphocytes and polymorphonuclear cells. There were swelling of the capillary endothelium and necrosis of vascular endothelial cells, often accompanied by thrombosis. In addition to these blood-vessel changes, the heart muscle showed a slight interstitial inflammatory reaction of variable density, with fragmentation of The liver showed moderate fatty muscle fibers. changes. Evidence of a lobular pneumonia was found and the exudate within the alveoli was seropurulent in character and apparently free from fibrin. These histologic changes are in accord with those recorded by Lillie.11

#### Serology

Serologic studies were carried out on sixty-nine blood serums from the twenty-six patients with Proteus strains (X 19, X 2, and X Kingsbury).

The Proteus X 2 and X Kingsbury strains were obtained from the National Collection of Type Cultures through Dr. A. Felix of the Lister Institute, London. The strain X 2 (No. 32282) was an Ovariant, and OX Kingsbury strain (No. 32274) later showed an O-HO reversion and was used in this The X 19 (No. form for the agglutination tests. 211) was the O-variant from a single colony fished

from the O-variant received originally from Dr. Mooser of Mexico City. The antigens12 prepared from these cultures were alcohol-treated suspensions of an opacity equal to that of the barium-sulfate standard No. 3. From one to four blood specimens from each patient were examined. The tests with unheated serums were incubated for two hours at from 35 to 37 C. and then refrigerated for from sixteen to eighteen hours. The agglutinative titers of a representative number of the serums with these Proteus X strains are recorded in Table 1.

Marked agglutination of Proteus OX 19 was obtained (see Table 1) with the serums from twentyfour patients and partial agglutination with the serums from two; marked agglutination of OX 2 also occurred with the serums from four of the patients and partial agglutination with serums from eight, the agglutinative titer being definitely higher in two instances with this strain than with OX 19. Proteus X Kingsbury was not agglutinated in significant titer by any of the serums.

It is also important to note the fluctuations in the titers of the reactions of the serums. The titers of specimens collected during the first week of illness ranged from 0 to 1:80, while titers from 1:160 to 1:2,500 were obtained with specimens collected between the second and third week after onset. Davis, Parker, and Walker,13 and more recently Parker,6 have emphasized the importance of examining multiple blood specimens from spotted fever patients. They point out that a single specimen collected during the first week of the disease is of little value, but evidence of a rise in agglutinative properties of the serum during the course of the disease may be of definite aid in diagnosis.

#### Summary

Serologic studies of multiple blood specimens from twenty-six residents of rural sections of Long Island with clinical and epidemiologic evidence of Rocky Mountain spotted fever are reported. Agglutination tests were performed using Proteus straine OX 19. OX 2, and X Kingsbury (this strain showing an O-HO reversion).

Marked agglutination of OX 19 occurred with the serums from twenty-four of the twenty-six patients, and partial agglutination with the serums from the remaining two; marked agglutination of OX 2 was obtained with the serums from four, and partial agglutination with serums from eight.

Marked fluctuation of the reactions, which provides a definite aid in diagnosis, occurred in many instances and the agglutination of OX 2 by some of the serums helped to differentiate Rocky Mountain spotted fever from endemic typhus.

This report supplements a study completed in 1935 with specimens from ten other patients on Long Island whose histories were suggestive of Rocky Mountain spotted fever; thus a total of thirty-six cases have been studied serologically since 1926.

#### FAMILY SECURITY THEME OF PLANNED PARENTHOOD MEETING

"Family Security—A Basis for World Security" will be the theme of the twenty-eighth annual meeting of the Planned Parenthood Federation of America at the Waldorf-Astoria Hotel in New York City, January 24-27, 1944. Representatives of planned parenthood, state leagues, and local committees in all sections of the country will take

The question "Can We Build a Permanent Peace in an Overcrowded World?" will be discussed by noted speakers and postwar planners at the annual dinner on the evening of January 26 spokesmen for war workers, the armed forces, the Segro population, and other groups in modern society will be presented at a luncheon meeting on the theme "Parenthood—As Young America Wants It," on January 25.

Workshop sessions, to be held on January 25, 26, and 27, will bring together experts on planned parenthood and related subjects. They will consider a number of current and contemplated projects, including programs in the fields of social work, medicine and public health, industrial hygiene, nursing and religious leadership

Planned Parenthood services are available to the public through private physicians, 794 clinics, and the public health programs of seven states. The Federation and its affiliates serve thousands

of nurses, clergymen, and social workers each

Its activities in behalf of improved maternal health, child spacing, and planned families have been greatly increased since the beginning of the

#### HOW TO PREVENT COLDS

In 1908 my father built a sleeping porch on our house. We would all sleep out there in the winter, if it got cold enough, he said, and we wouldn't have any more colds So we all slept out on the sleeping porch. All I can remember about it now is that we had fun out there but I was tired all the time and was glad to get to school where I could sleep.

Then we started taking cold baths. My father ngged up a rubber shower contraption so that shower first thing in the morning. That was so that we wouldn't have any more colds. Cold shower work or the colds of the cold showers went on for quite a while and were very jolly. Every body slapped and snorted and shrieked in his turn and then waited to hear the next victim. We caught father using some warm water one morning, so the whole system broke down. I don't

remember having any colds in those days but that was forty years ago.

When I got older and left home, I didn't do anything about colds except carry a handkerchief. Those were busy, exciting days in which I don't

Those were busy, exching days in which I don't remember about colds. Otherwise occupied.

Now, in the year 1943, my wife says we should do something so the children won't have colds. She turns to me because I am a doctor and she doesn't know any better. Well, let's see, there have been quite a few fads about colds. Sunlamps, codliver oil, vaccines, and now we sleep with the windows closed. I think maybe the best thing would be to build a sleeping porch where the kids can take up the family pillow fights where they left off in 1910. I don't remember any colds then-or much of anything else. - L. M. D., in Journal-Lancel

# Therapeutics

#### CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the February 1 issue and will concern "Treatment of Edema by Drugs."

## Principles of Treatment of Edema and Dehydration

DR. McKeen Cattell: The problem of maintaining a normal distribution of body water is basic to a great many clinical conditions. Rational therapy is based upon a knowledge of the physiologic mechanisms concerned and the conference today will attempt to review these principles and lay the ground work for the conference next week, which will be on the treatment of edema by drugs. Today the topic is the "Principles of Treatment of Edema and Dehydration," to be introduced by Dr. Barr.

DR. DAVID P. BARR: It is a brave, and I think a foolhardy clinician, who will permit himself to speak on hydration and dehydration before this group.

Proup.

Edema, as all of you know, is an increase in extracellular water. Both in its generalized and in its local forms, it is an extraordinarily common symptom. The phenomenon has always attracted attention, and it is indeed remarkable that the ability of a normal person to drink water in large amounts without obvious change in his superficial tissues may be so completely lost that repeated ingestion of even small volumes of water may result in massive edema.

The first comprehensive attempt at an explanation of edema was made by Ernest Starling. In 1896 he published an article in the Journal of Physiology in which he stated his belief that the capillary wall was a membrane which was freely permeable to water and most crystalloids. He confirmed the long-held and rather obvious opinion that the chief force driving water from the blood stream was the intracapillary pressure, and he advanced the hypothesis that this was opposed by the colloidal osmotic pressure of the proteins, which could not pass through the membrane. It was Starling's idea that hydrostatic pressure tended to force fluid out of the capillaries, while the osmotic pressure tended to hold it in. This hypothesis of one of the world's greatest physiologists has stood the test of nearly fifty years, and it is accepted today with only minor modifications.

In the Starling hypothesis everything depends upon the properties and integrity of the capillary walls, which are truly remarkable structures. They appear as thin layers of endothelial cells but, as August Krogh and Sir Thomas Lewis have shown, they have an active function. They are independently contractile and are capable of responding individually and in a discriminating manner to the circulatory needs of tissues. According to Krogh's calculation their total area in a normal man approximates 68,000 square feet, or one and one-half acres. Among membranes in the animal body they seem to be unique in that they permit the passage of water and most crystalloids, including sodium and potassium salts, as well as sugar, urea, creatinine, and amino acids. They do not pass proteins and in their normal state are about 95 per cent efficient in holding them back. Passage both of crystalloids and of water is accomplished more rapidly than by most membranes. Landis figured that the capillary membranes pass water three thousand times more rapidly than the ordinary cell membrane and one hundred times more rapidly than does the membrane of a red blood cell. Landis also calculated that with the acre and a half of extremely permeable membrane and a hydrostatic pressure of only 10 mm. Hg any one of us should be able to filter out in ten seconds all of the water from his blood stream if there were no opposing force.

From the excellent studies of Krogh and others it is apparent that the amount of water which can actually pass out through the membranes will be dependent upon a number of factors including the total area of the capillary wall, the permeability of the membrane, and the balance between hydrostatic and colloidal osmotic pressure. Some evaluation of these factors is necessary to the understanding of clinical edema.

Estimation of intracapillary hydrostatic pressure is unsatisfactory, and direct measurement has been extremely difficult. Recently, however, Robert Chambers has accomplished the extraordinary feat of cannulizing individual capillaries

with capillary pipets of a diameter at the end of only 0.004 to 0.008 mm. Among other things he has shown that the capillary pressure in normal individuals varies from approximately 35 mm. at the arteriolar end to from 14 mm. to 13 mm. at the venous end. He found, as could have been predicted, that the capillary pressure was variable from minute to minute, that it differed in adjoining capillaries even though they might arise from the same arteriole, and that the pressure was dependent upon changes in systemic pressure, arterial pressure, and also on the state of venous pressure.

It is obvious that the intracapillary pressure can be increased either by vasodilatation of arterioles or by increasing venous pressure. Actually, changes in the arteriolar pressure are less potent in the production of edema than are variations in venous pressure. It is true that fluid may escape into the subcutaneous tissues and into the intercellular tissues following the application of heat or other methods of vasodilatation. Usually, however, the edema is not extreme. On the other hand, a venous pressure maintained in the arm at 80 mm. of mercury by means of a blood pressure cuff causes an enormous accumulation of extracellular fluid which is limited only by the increasing concentration of protein and the consequent rise in colloidal osmotic pressure within the capil-

The colloidal osmotic forces which oppose hydrostatic pressure are derived chiefly from albumin which, because of its small molecule, is about four times as effective in holding the water in the blood vessel as is globulin. The osmotic pressure of a 1 per cent solution of albumin is 5.5 mm., whereas a 1 per cent solution of globulin exerts a pressure of only 1.4 mm. The total osmotic pressure of the blood in the capillary averages about 25 to 30 mm. of mercury. This may be compared with 35 mm. of hydrostatic pressure in the arteriolar end of the capillary loop, and with 13 mm. of hydrostatic pressure in the venous end.

The experiments of Louis Leiter and of many others have shown that visible edema tends to develop if the total protein of the blood falls far below 5 Gm. or if the albumin fraction falls below 2 Gm. It is obvious that this is only an approximation, because the force of osmosis must be modified by forces of a most diverse character, either supporting or opposing it. Possibly it is more correct to say that any reduction in the protein and particularly in the albumin of the plasma tends to increase the amount of fluid in the tissues.

There have been many criticisms of Starling's hypothesis, most of which have arisen because

James P. France

the original statement was interpreted too literally and factors other than the two opposing forces of hydrostatic pressure and colloidal pressure were not sufficiently considered. Actually many other forces contribute to the development of edema.

One of these is the pressure in the tissues about the capillary walls. Its potential importance is easily demonstrated. Capillaries can be completely closed by external pressure. On the other hand, cupping, so much practiced by older physicians, produced a rapidly accumulating localized edema because of the negative pressure which the method produced in the tissues. Fat in the subcutaneous tissues exerts an influence and large accumulations of fat tend to limit edema. On the other hand, in an area like the under lid where there is no fat and the skin is very loose, fluid can escape because it is unopposed by tissue tension.

A second influence which modifies importantly a strict interpretation of the Starling hypothesis is the lymphatic circulation. It is only recently, through the studies of Dr. Mc-Master and others, that we have begun to realize how extremely important this factor may be. Lymphatic vessels are so numerous that one cannot stick a pin anywhere in the skin without rupturing several of them. The amount of fluid which can be carried away by the lymphatic circulation as a whole is extremely great. The fluid of the intercellular spaces tends to pass into the lymphatics because of the high protein content of lymph. Once started, the flow is maintained by a system of valves which prevent return of fluid to tissue spaces. It has long been known that blocking of the lymphatics alone, without modification of other factors, may cause massive edema. In considering factors contributing to edema it is therefore just as important to regard the state of the lymphatics as it is to evaluate the hydrostatic, the colloid, or the tissue pressure.

It is apparent that the entire mechanism which we have been discussing must be dependent also upon the intact capillary membrane. Starling assumed a membrane which was 95 per cent effective in holding in proteins. Any chemical, mechanical, thermal, or anoxemic injury of the epithelium of the capillary walls will tend to increase the permeability of the membrane. It is possible to injure the capillary walls to such an extent that the proteins pass freely from the blood into the subcutaneous tissues, thus eliminating as a factor the differential colloidal osmotic pressure. Under such circumstances the water may pass at least seven times as rapidly as it does through an uninjured membrane.

Still one other factor of great significance must be considered. This is the role of sodium chloride in the production of edema. It is common knowledge that when one ingests salt, thirst follows and water is drunk. If one ingests more salt, thirst is increased, and more water is taken. In the normal individual, however, it is quite difficult to produce any visible edema of the tissues even after enormous salt and water in-That the difficulty may be overcome, however, has been demonstrated by the sot who persistently salts his beer and eats pretzels while he is drinking. Assiduity in this occupation may result in a quite massive edema, which subsides rapidly without sequela in a few days. Under any circumstances, the amount of salt in the body is a most important influence in determining the degree of hydration. Accumulation of salt increases water storage; loss of salt causes dehydration. Since salt passes freely back and forth across the capillary membrane, the water held by each increment of salt distributes itself between plasma, intercellular spaces, and lymphatics. Nevertheless, when edema exists from any cause, its amount is automatically increased by accumulation of salt. Contrariwise, the elimination of salt from the body is one of the most effective means of combatting abnormal accumulations of fluid in intercellular spaces. It should also be emphasized that while all salts play a role in the hydration of the body, the chief factor is sodium chloride; furthermore, that because of the free interchange of chlorides and carbonates, the concentration of sodium itself is the most important single influence in determining the amount of water stored in the

In considering clinical edema it is necessary to take into account all of the factors which have been mentioned. The various forces—intracapillary blood pressure, colloidal osmotic pressure, lymphatic drainage, the state of the capillary membrane, and the total amount of salt in the body—combine to determine the amount of water which will be found in the intercellular tissues at any one time. The complicated interplay of factors may be illustrated by listing some of the abnormalities that may contribute to cardiac edema:

1. Increased venous pressure causes increased intracapillary blood pressure and also retards lymphatic drainage.

2. Hemodilution, often seen with increased blood volume, decreases the amount of the protein of the plasma and consequently diminishes its osmotic pressure.

3. Dilatation of capillaries increases the area of the capillary membrane and thereby the area for filtration.

4. Anoxemia of severe cardiac failure injures capillary membrane and increases its permeability to protein.

5. Malnutrition, a factor in some cardiac patients, may diminish the concentration of plasma proteins and so lessen colloidal osmotic pressure.

6. Loss of weight from malnutrition, with consequent loss of fat in the panniculus, decreases tissue pressure.

7. Edema itself may interfere seriously with lymphatic drainage.

8. Salt, if given unwisely to cardiacs, or even if permitted in normal amounts, will augment the collection of water in extracellular spaces.

Dr. Cattell: I think Dr. Barr is now ready for questions or comments from the group. His formulations raise a number of questions for the pharmacologists, and I would like to ask Dr. Gold whether this general picture is adequate to cover the mechanisms through which drugs act in relieving edema.

Dr. HARRY GOLD: From the standpoint of the use of drugs in the treatment of edema the emphasis upon salt is extremely important. We usually think of edema as an increase in water of the tissues, but what edema is in fact is an increase of the whole solution. The extracellular fluid is not only water. It is a composite of salts in a fixed concentration with an increased amount of all the solid ingredients which go into the extracellular fluid constituting the edema fluid. For that reason we have to consider in relation to the action of the diuretics what they do to salt excretion, not only what they do to water excretion. It may be well to consider the question whether some diuretics do not exert a primary action to increase the excretion of salt and that water follows. It may well be that in heart failure, for example, in which edema is outstanding, the primary trouble may be a diminished capacity of the kidney to excrete salt, or salt is being held in the tissues for some other reason, and that the primary point of attack, whether it is in the kidney or in some other organ, needs to be directed to the excretion of salt.

DR. WALTER MODELL: There are two paradoxes I would like Dr. Barr to discuss. One is the existence of edema and dehydration at the same time, and the other is the treatment of edema as Newburgh did many years ago with water, and which has since been advocated by Schroeder.

DR. C. H. WHEELER: I would like Dr. Barr to explain why it is generally considered inadvisable to give a patient with cardiac edema, for example, substantial amounts of sodium salts, whereas many physicians have no hesitancy in giving patients with cardiac edema potassium chloride or potassium citrate in place of sodium chloride.

I would also like to ask whether there is any information available about the optimal rate at which a healthy, young adult may be hydrated. For example, given a healthy young soldier in the desert who is extremely dehydrated, how fast is it safe to hydrate him?

Dr. CATTELL: Dr. Barr, you have plenty to start with.

Dr. Barr: Unfortunately, I shall be unable to answer all of these interesting questions. I should like, however, to speak a moment about dehydration, which is relevant to Dr. Modell's first question.

Dehydration may arise from either of two causes: First, it is obvious that if the body is deprived of water it will become dehydrated. We lose every day in our insensible perspiration, in our urine, and in our stools, a certain amount of water which must be replaced. The most prominent symptoms of dehydration from deprivation of water are extreme thirst and oliguria. Circulatory collapse is not frequent. There is much evidence to indicate that in this form of dehydration the cells of the body and the intercellular spaces share equally in the water depletion.

The second form of dehydration depends upon a depletion of base and particularly of sodium. If for any reason the body loses sodium, its ability to hold water is correspondingly decreased. This form of dehydration is observed in the adrenal insufficiency of Addison's disease. Following a large and prolonged loss of sodium from the body, there is hemoconcentration, great loss of the intercellular fluid, profound asthenia, low blood pressure, and circulatory collapse. Thirst may be entirely absent, and yet the dehydration may be as complete as if the body had been deprived of water over a long period. Loss of water from cells is not as prominent a feature as is hemoconcentration and dehydration of intercellular spaces. When we speak of dehydration it is necessary to take into account both the factors of salt loss and water loss, and the two clinical syndromes which may result from them.

How can we have edema and dehydration at the same time? It is obvious, if we have edema, that there are some parts of the body which are being hydrated. In other words, the intercellular tissues have plenty of water but there may be at the same time a considerable degree of hemoconcentration because of the loss of water from the blood stream to tissues. If this is due, as it usually is, to loss of protein from the

blood stream, the defect is irreversible. For the time being, the blood cannot be rehydrated. If the edema depends upon injury and increased permeability of the capillaries, to such an extent that protein has escaped from the blood stream, there may be loss of water in the capillaries with increase of water in the intercellular tissues. Again dehydration and edema are existing simultaneously in different parts of the body.

79

I am interested in Dr. Wheeler's question. Is it dangerous to give water rapidly to a man who has long been deprived of water, and if so, why? I am not sure I know the answer. It is true that many men who have suffered prol. \_ged thirst have also been seriously undernourished. If there is a degree of malnutrition and a loss of protein from the blood plasma, water which is introduced rapidly into the body does not stay in the blood. It escapes through the capillary walls into the intercellular tissues. Under such circumstances it seems possible that cerebral edema with convulsions or pulmonary edema with sudden death might arise. I am not sure whether there might also be danger to a fellow who is not malnourished but is simply dehydrated. I am wondering if you have any data on this point, Dr. Cattell? Do you know whether in simple dehydration the administration of large amounts of water is dangerous?

DR. CATTELL: It is possible that the kidney is incapable of adjusting itself to a sudden increase in the water intake with sufficient rapidity, though I believe that if the kidney is functioning normally it could readily cope with the rate of absorption from the gastrointestinal tract. But we do know of a condition which we speak of as water intoxication. There are conditions of deficient salt concentration or disturbed renal function that might lead to difficulty.

VISITOR: Isn't the problem essentially the same as that of heat cramp, which arises from the depletion of sodium? With progressive dehydration from water loss there may also be loss of sodium. Rapid replacement of water without corresponding increase in salt may produce hypotonicity in the body and precipitate heat cramps.

DR. CATTELL: What are the possibilities of replacing water too rapidly by means other than by injection?

VISITOR: I think that the man on a raft who had been deprived of water for a long time could take isotonic sodium chloride solution in amounts sufficient to hydrate him.

Dr. Gold: I think that explanation also applies to Dr. Modell's question concerning the effectiveness of water as a diuretic in massive edema. It all comes back to the point that the edema fluid is not merely water. Edema fluid is a

solution of water and salts. If one gives a great deal of water one dilutes the salts in the spaces. This dilution excites the kidneys to excrete water, but the kidneys do not obtain the same stimulus from the administration of a solution of salt and water. If water alone is given, the kidneys will excrete it together with tissue salts. Thus the edema is reduced by reason of the fact that the salt comes out of the intercellular spaces. Six or 7 liters of water given to a person with waterlogged tissues often produce a rapid disappearance of the edema.

In this connection I would like to mention still another example of the coexistence of edema and dehydration. In cardiac patients with congestive failure there may be a concentration of salt in the tissue interspaces due to the fact that the body has difficulty in eliminating salt. The salt draws fluid from the cells as well as from the blood stream in order to maintain osmotic equilibrium. This produces at the same time edema and tissue desiccation. When the brine around the cells is reduced, as it may be, by restricting salt and giving the patient water freely, the edema is relieved and the tissue cells are hydrated by the same process.

Dr. Barr: I think the work which Schroeder did at the Rockefeller Hospital is important. As you know, we tend to limit the water intake of our cardiac patients. Schroeder showed that the daily administration of 3,000 cc. of water would actually cause diuresis in a severely decompensated cardiac patient if the intake of salt were kept below 1 Gm. in 24 hours. His work confirms Dr. Gold's contention that under certain conditions of salt equilibrium water is one of the most effective of diuretics.

Dr. Modell: In Newburgh's nephritics, who were studied much earlier than Dr. Schroeder's patients, edema seemed to depend on difficulty in concentrating urine, with the result that salt in the body was accumulated and caused edema. As soon as they were deprived of salt and ingested sufficient water, diuresis resulted, and edema quickly disappeared.

DR. CATTELL: There seems to be some hesitation in answering Dr. Wheeler's other question about sodium in edema. Why do we deprive our cardiacs of sodium chloride but give them potassium chloride?

Is it not because potassium promotes the elimination of sodium? It is not stored either in the blood stream or in tissue interspaces, but is distributed throughout the body, and then quickly eliminated. In the internal readjustment, as in the case of any electrolyte in excess, there is an increased excretion of an equivalent amount of electrolyte in the form of both sodium and potassium with a resultant actual loss of

sodium. Potassium may also be taken up by the cells, but as far as I know can play no part in the production of edema.

DR. WHEELER: Do we know why, when the body is starving for base, so to speak, if we then give potassium, the body does not use it? Do we know the fundamental reason why in such situations the body cannot use it?

DR. CATTELL: I think Dr. Modell has some ideas on that.

Dr. Modell: I suspect that some of the difficulty in accepting a pharmacologic difference between sodium and potassium lies in their close chemical relationship; both are bases and they are in the same group in the periodic table. Biologically, however, they are different. Sodium cannot pass through most cell membranes, while potassium can. Sodium is relatively difficult for the body to eliminate, potassium is very quickly eliminated.

Since sodium cannot pass through the cell membrane, but remains outside it, it holds water in order to maintain osmotic equilibrium. Thus it favors the accumulation of extracellular fluid; in other words, edema. Potassium, on the other hand, does not bind extracellular water, because it diffuses into all the fluid compartments and thus exerts no differential osmotic pressure. Hence it cannot produce edema; rather it is a diuretic. Sodium is the hydrating base, potassium is the dehydrating base.

In a condition such as that described by Dr. Wheeler, in which the body is starving for base, any base might do if all that was wanted was base. However, if we take a concrete example, the reason for a specific choice will perhaps be apparent. In diabetic acidosis, base is driven out of the body and the alkali reserve is depleted. What must not be overlooked is that the acidosis, the driving out of fixed base from the body, results in dehydration at the same time. while any base might be used to combat the acidosis itself, basic sodium salts are the drugs of choice because they combat the dehydration process at the same time. Their slow elimination also makes them especially useful here. If potassium were used in this condition, the state of dehydration would be aggravated. Sodium, therefore, is the desirable base, not because it is more of a base but because of the other special features of sodium. For the same reason it is not used in cardiac edema. In edema, on the other hand, potassium may be helpful, for as already explained, it drives sodium and consequently water out of the body.

In adrenal cortex insufficiency the distinction the body makes between sodium and potassium is very clear; the Addisonian excretes sodium and stores potassium. As a result he becomes dehydrated. You treat him in exactly the opposite way that you would a patient with cardiac edema. You put him on a high sodium, low potassium diet, and thus you hydrate him.

Dr. Cattell: As a matter of fact, potassium is extremely toxic. An appreciable increase in blood levels cannot be obtained without producing convulsions and cardiac irregularities.

STUDENT: What are the uses of potassium in dehydration?

Dr. Barr: If the dehydration were due to a loss of sodium, the administration of potassium would undoubtedly aggravate the condition because it would, as has just been pointed out, cause an increased excretion of sodium and its tendency would be to increase the excretion of water.

In dehydration arising from deprivation of water without the loss of salt, potassium salts could not be helpful, since their tendency to cause loss of sodium would also increase dehydration. Would you agree, Dr. Cattell?

Dr. CATTELL: Yes.

こうハンス・

12

1

? \* Dr. Barr: I can't think of any condition of dehydration in which the potassium salts would not be potentially injurious.

DR CATTELL: There is the thought that the important element in retaining normal osmotic relations of the cell is the potassium inside the cell to balance the sodium outside. I have no idea whether there is any advantage in having potassium available for the purpose of balancing the higher concentration of sodium outside the cell present in dehydration, and thereby maintaining the normal osmotic relationship.

Dr. R. F. Pitts: There is an interesting paradoxic treatment of cardiac edema which highlights Dr. Gold's idea on the prominent role of sodium. It is possible in a patient with mild cardiac edema to start the process of diuresis by the administration of posterior pituitary hormone

Posterior pituitary hormone has two effects: to increase readsorption of water by the renal tubules, and to increase the excretion of sodium. By causing the cardiac patient to lose sodium, although reabsorption of water is temporarily increased, a state of imbalance between the sodium and the water in the body is produced. The readjustment of this imbalance often may,

after the antidimetic effect has ceased, be followed by a surprisingly satisfactory dimesis and a decrease of edema.

#### Summary

Dr. Modell: This conference has uncovered opinions on practically all the factors which may contribute to the production of edema and dehydration. A foundation has thus been laid for the rational treatment of these conditions.

The widely recognized hydrodynamic forces which may produce edema and the clinical conditions in which they may be found have been discussed. It was pointed out that increased venous pressure, increased intracapillary pressure, increased capillary permeability, decreased colloid osmotic pressure, lowered serum proteins, decreased tissue tension, and impaired lymphatic drainage all may play a role in the production of edema.

In addition water and sodium, slighted by many perhaps, were today mentioned as ranking in importance with the forces already listed. The ability of sodium to bind water has been emphasized. It was pointed out that the elimination of sodium from the diet may, in patients with edema, produce a diuresis, and conversely in states of dehydration, such as in adrenal cortex insufficiency and in diabetic acidosis, sodium is beneficial because it favors water storage. The point was raised whether some diuretics do not act primarily by increasing the elimination of stored sodium, with water diuresis following as a consequence of the primary sodium loss.

It was shown that potassium, the close chemical relative of sodium, is its pharmacologic antithesis, since it is diuretic in action and favors dehydration and the elimination of sodium. A biologic basis for the pharmacologic difference was advanced.

That water itself may be exceedingly useful in the elimination of massive edema in suitable cases as well as in the treatment of dehydration was also brought out.

The discussion served to emphasize that an understanding of the causes of edema and dehydration may, in each case, not only make possible a therapeutic solution of a particular problem but may also simplify therapy considerably.

#### FORUM ON ALLERGY

The sixth annual forum on allergy will be held in the Hotel Statler, St. Louis, Missouri, on Saturday and Sunday, January 22-23.

There will be fifteen study groups, as well as lectures, pictures, demonstrations, and panel discussions.

# Postgraduate Medical Education

Programs arranged by the Council Committee on Public Health and Education of the Mcdical Society of the State of New York are published in this section of the Journal. bers of the committee are Oliver W. H. Mitchell, M.D., Chairman (428 Greenwood Place, Syracuse); George Baehr, M.D.; and Charles D. Post, M.D.

#### Industrial Medicine

LECTURE on industrial medicine was given A before the Jefferson County Medical Society. The meeting was held on Thursday, December 9, 1943, at the Black River Valley Club in Watertown, New York.
"Industrial Dermatoses" was the title of the

lecture; Dr. Leon H. Griggs, associate professor of clinical medicine at Syracuse University College of Medicine, was the speaker. This instruction was provided by the Medical Society of the State of New York with the cooperation of the New York State Department of Health.

#### Angina Pectoris and Coronary Occlusion

A SINGLE lecture on general medicine was presented to the Greene County Medical Society on Thursday, December 23, 1943, at 9:00

The lecture took place at the Memorial Hos-

pital of Greene County, Catskill

The subject was "What Can We Do for Angina

Pectoris and Coronary Occlusion?" The lecture was delivered by Dr. Clayton W. Greene, professor of medicine at the University of Bulialo School of Medicine in Buffalo.

The Medical Society of the State of New York and the New York State Department of Health

jointly provided this instruction.

#### Tropical Medicine

THE Broome County Medical Society will hear two lectures on tropical medicine on Tuesday evenings in January and February, at 8:30 P.M., in the Doctors Memorial Building, Binghamton City Hospital, Binghamton.

On January 11, 1944, Dr. Barton F. Hauenstein will speak on the subject, "The Present and Postwar Importance of the Dysenteries." On February 8, 1944, the lecture "The Importance of Early Diag-

nosis and Treatment of Falciparum Malaria" will be given by Dr. Harry Most, professor of clinical pathology and assistant professor of preventive medicine at the New York University College of Medicine.

This instruction is presented as a cooperative endeavor between the New York State Department of Health and the Medical Society of the State of

New York.

#### WOMEN WAR WORKERS AND PREGNANCY

A three-month survey of women war workers in industry in eleven states was recently completed by Dr. Charlotte Silverman of the staff of the Children's Bureau. She visited 73 industrial plants where about 273,000 women are employed, and her study was concerned chiefly with the question

of maternity leaves and maternity care.

Dr. Silverman found that generally the industries kept inadequate records of pregnancy among their employees. Records were kept only in the larger industrial plants and in those which had employed women for years. Of the 73 firms studied, 64 were found to have fixed policies in regard to pregnant employees. In 19 of these, pregnant women were discharged either immediately on discovery of the pregnancy, or from two to six months later, or on the advice of the company physician. In 45 plants there was a fixed policy of leave of absence either on discovery of the pregnancy or within certain limited periods. The most lenient were the textile companies, which have for many years permitted pregnant women to work as long as they wished and to return to work when they so desired.

Of the 73 companies studied, only 26 could furnish records of the pregnancies among their employees; the others could give only estimates. On the basis of these figures the incidence of pregnancy was calculated to vary from 3.2 to 6 cases per 1,000

women working per month.

The question of pregnancy as related to women's war work has also become acute in England, where a very large number of women have taken an important place in industry. As the London correspondent of the Journal of the American Medical Association (November 7, 1942) points out, some firms send expectant mothers off duty for some weeks before and after labor, but others do not. Many women however do not willingly give up Many women, however, do not willingly give up their work because of financial considerations, yet the health of the mother during the last weeks of pregnancy and during lactation is of profound

importance to the future of the country.

The National Council of Women has requested the Ministry of Health for special financial allowances for women under these circumstances. The Council holds that a woman should not be working in any paid employment during the last eight weeks

of pregnancy and the first eight weeks of lactation.
The National Insurance Act of England does not recognize pregnancy as incapacitating from work and therefore the pregnant woman is not qualified for sickness benefits. The suggestion was therefore made that insurance benefits should be paid to insured pregnant women. The Council wishes the insurance companies to recognize the last eight weeks of pregnancy as a period of in-capacity within the meaning of the insurance act. -Human Fertility

#### City Health Agencies Start X-Raying of Employee Groups

THE New York Tuberculosis and Health Association, in cooperation with the New York City Department of Health, inaugurated its program of mass x-raying of employee groups on December 1 at the Breslee Manufacturing Company, which is the first firm in Manhattan to avail itself of the Association's new service. The program also provides for a follow-up service for those whose x-rays reveal positive or suspicious findings.

The Breslee Manufacturing Company, which produces critical war material, has 750 employees at its 151 West 26th Street and 3 West 19th Street

š

Arthur A. Gardner, president of the Breslee

Company, said that the suggestion for the x-raying was made by an employee through the company's labor management committee and that before December 1,85 per cent of the personnel had given written consent for the examinations. Because many employees have asked that members of their families be included, Mr. Gardner has arranged to have them present also when the x-ray pictures

The x-raying of Breslee's employees, Mr. Gardner said, is another of the management's services to its employees in expediting war production. Among other services is a vitamin bar and an in-

firmary with a full-time nurse in attendance.

#### General Magee Heads Medical Information Office

MAJOR General James Carre Magee, Medical Corps, United States Army, retired, has been named executive officer of the information service of the division of medical sciences of the National Research Council. He assumed office on December 1.

General Magee will devote his full time to the organization of a central office in the National Research Council which will collect medical reports and records dealing widely with military medical practice, civilian practice as affected by the war, medical education and research, and the distribu-tion of diseases. This material, so far as military necessities permit, will be made available by publications, summaries, and notes.

This service has been established by the Council under the recent grant of the Johnson & Johnson Research Foundation of New Brunswick, New Jersey, by which \$75,000 was made available to the Council to enable it to assemble and disseminate, as far as possible, medical information pertaining to the war effort. This enterprise is expected to fill a long-felt need in providing up-to-date information to the medical officers of the armed information to the medical officers of the armed services both in this country and abroad and in making the experience of war medicine available as far as possible to civilian physicians.

General Magee has had a distinguished record

in the Medical Corps of the Army. A graduate of Jefferson Medical College in 1905, he has spent his entire professional life in the medical service of the Army. He was assigned to the Philippines before the outbreak of the first World War and then recalled for European duty from 1917 to 1919. He was appointed Surgeon General of the Army in 1939 and on May 31, 1943, he was retired on completion of the four-year term of duty. It was under his direction that the Medical Corns was under his direction that the Medical Corps was enormously expanded to meet the demands of the present war and the program of service adopted which has led to the remarkable health record of the Army. General Magee holds the honorary degree of Doctor of Science from Jefferson Medical College, and was recently awarded the Distinguished Service Medal for outstanding services as Surgeon

The citation for the Distinguished Service Medal said that General Magee's "farsighted and dynamic energy was greatly responsible for our soldiers being able thus far to emerge from battle with the lowest mortality rate among the wounded in our history," and pointed out that "the Army has benefited greatly from his eagerness to avail himself of the most expert advice and data from the civilian medical profession in the fields of research against epidemics."

#### Postgraduate Course in Industrial Medicine at Long Island College

EIGHTEEN physicians who completed the second postgraduate course in industrial medicine at the Long Island College of Medicine, Brooklyn, on November 12 are undergoing super-vised training periods of one to four weeks in the medical department of industrial

vised training periods of one to four weeks in the medical departments of a number of industrial concerns in New York, New Jersey, and Massachusetts, according to a report issued by the College. The companies where the training is being conducted are Bell Telephone Laboratories, Consolidated Edison Company, and Western Electric Company, New York City; American Cyanamid Company and Merck & Company, Inc., New Jersey; and the Norton Company, Worcester, Massachusetts. Massachusetts.

Seventy-two matriculants from five states, including members of the armed forces and the U.S. Public Health Service, enrolled for the two weeks' course of lectures and clinics under the auspices of the Department of Preventive Medicine and Community Health. Sixty-four of the matriculants were from New York State. Thirty-three authorities in the field of industrial medicine and surgery joined with members of the College staff in presenting the afternoon and evening lectures.

Clinics were held each morning from November 2 to November 12. They included two given at the College by the departments of surgery and radiology and others in the medical departments of the American Telephone and Telegraph Company, Metropolitan Life Insurance Company, Nassau Smelting and Refining Company, Sperry Gyroscope Company, and the New York State Department of Labor's Bureau of Industrial Hy-giene. The New York State Compensation Medical Bill Arbitration Board held a special hearing at the College for the benefit of matriculants.

The first week of the course was devoted to a

study of the organization and administration of industrial medical departments in small and large plants, the technic of physical examinations, occupational diseases, compensation laws, industrial

hazards, and plant sanitation and hygiene.

During the second week the course stressed special problems of industrial toxicology, accidents and rehabilitation, health education, nutrition, and industrial health insurance programs. The clinics were arranged to demonstrate and apply

the didactic material of the lectures. Among the companies from which members of medical staffs enrolled for the course were the Babcock & Wilcox Company, Ohio; Brooklyn Union Gas Company, Mergenthaler Linotype Company, Brooklyn; National Biscuit Company, Brooklyn New York; Travelers Insurance Company, Connecticut; E. R. Squibb & Company, Brooklyn; and Todd Shipyards, New York.

The report pointed out that the College had given this course for the second consecutive year as a contribution to the war effort and that seventytwo enrolled this year compared with fifty-nine in

1942

Designed as an orientation course for physicians engaged in or desiring to enter industrial practice, the course has become of increasing importance in the training of physicians for war industries. Five of the physicians enrolled last year have secured full-time positions with industrial concerns, four of which are engaged in war production, the report stated, and many other firms with war work enrolled one or more physicians.

A binder containing the complete texts of the lectures is in preparation and will be available for purchase from the College after December 31.

Through a register of industrial physicians now maintained by the Department of Administration, further help to industrial concerns seeking medical personnel has been provided by the College. The register is consulted by these concerns and a selection made of candidates, who are then contacted.

The report was prepared by Dr. Thomas D. Dublin, associate professor and head of the Department of Preventive Medicine and Community Health, and Alfred R. Crawford of the Department of Administration, who served as secretary of the

"The Representative Committee of the British Medical Association advocates as a step forward in Great Britain the extension of the National Health Insurance Plan to include the dependents of insured persons and others of like economic status, and to

cover consultant and specialistic services and laboratory and hospital facilities, as well as general practitioner services. This statement indicates at once how completely lacking has been the National Health Insurance Plan in approximating anything resembling the quality of medical service that prevails in the United States. This recommendation again emphasizes that the National Health Insurance Plan of Great Britain covers wage earners up to a certain level of income only, that it has not included the dependents, that it has not included others than wage earners of low economic status, that it has not provided consultant and specialistic service, or hospital facilities or laboratory service. The gradual development of prepayment plans in the United States has recognized the need for such services. The medical profession has approved prepayment plans to cover the costs of hospitalization, and also prepayment plans on a cash indemnity basis for meeting the costs of medical care. Certainly the gradual evolution in the practice of medicine that has taken place in this country has led to higher standards of medical practice and of medical service than are elsewhere available. The maintenance of the quality of the service is fundamental in any health program.

"The American Medical Association, through its House of Delegates, its Board of Trustees, and its Council on Medical Service and Public Relations, has urged again and again the continuing evolution of medical practice, based on sound experimentation. Already many state and county medical societies, many industries, and many insurance bodies have set up experiments of this type, some of which have already proved to be unsound. In this connection, therefore, the final recommendations of the Representative Committee of the British Medical Association, and of the Medical Planning Commission, deserve increased emphasis. They

say:
"There should be initiated, by arrangement and the and agreement between the government and the profession, organized experiments in the methods of practice, such as group practice, including health centers of different kinds, which should extend to general practitioner hospital units attached to general hospitals. Future developments in group practice should depend on the results of such clinical and administrative experimentation.

"Only by such controlled scientific experimentation can a sound system of medical service to meet the needs of all the persons in the community be

developed."

#### County News

Albany County

Dr. H. Charles Goldberg has retired as medical examiner and eye specialist in the workmens' compensation division of the State Labor Department. He held the state position for twenty-one years.

Dr. Goldberg will enter the private practice of

medicine in New York City.\*

Broax County

A regular meeting of the county society, held at Burnside Manor on December 15, featured a program on the Wagner-Murray-Dingell Bill. The speakers were Congressman Walter A. Lynch and Dr. Nathan B. Van Etten.

The North Bronx Medical Society held a meeting on December 16, which was sponsored on behalf of the Russian War Relief, the Russian War Relief Physicians' Committee, and the American-Soviet Medical Society. The program was devoted to a discussion of "Wartime Medicine in the Soviet Union" and included the first showing in the Bronx of the Society moving picture, "Experiments in the Revival of Organisms.

The meeting was addressed by Prof. Vladimir Lebedenko, U.S.S.R. representative of the U.S.S.R. Red Cross, and Dr. Gregory Zilboorg, psychiatrist.
Wives and friends of members of the society were

invited.

The effect of cold weather upon the circulatory system, and some of the ailments contracted from exposure to the cold, were discussed by Dr. Anna

<sup>\*</sup> Asterisk indicates that item is from a local newspaper.

Samuelson in a talk over Station WBNX on November 29. The broadcast was under the joint auspices of the Bronx County Medical Society and the Bronx Tuberculosis and Health Committee.\*

#### Broome County

The annual dinner meeting of the county society was held in the Art Gallery of the Arlington Hotel in Binghamton on December 14. Wives of mem-

bers of the society were guests for the evening.

The speaker was Dr. Hiram Gruber Woolf, former Episcopal chaplain at Cornell University who related his experiences under the rule of two

dictators-Hitler and Mussolini.

The outbreak of the war found Dr. Woolf serving the American churches in Munich and Dresden, as well as ministering to the English congregation in Berlin and acting as chaplain to the British prisoners of war in Germany. He spent six months incommunicado in the Regina Coeli prison in Rome and was sentenced to thirty years' imprisonment as an international spy. He returned to America in June, 1942.

#### Chemung County

Dr. R. Scott Howland, of Elmira, has been elected president of the Chemung County Medical Society, to succeed Dr. Florence S. Hassett.

Other officers are: Vice-president, Dr. William T. Boland; secretary, Dr. John H. Burke, Jr;

treasurer, Dr. M. Frederick Butler.

In a resolution on the death of Comdr. Charles L. Stevens, former Elmira physician, the society bore witness "to his character and high professional qualifications."
"Charley Stevens was thoroughly trained for

his high mission," the resolution continued.

"He was devoted to his profession, to his patients, and to his fellow men. He fully measured up to what Rudyard Kipling describes as a profession of high ethics and lofty ideals which exacts from its followers the largest responsibilities and the highest death rate," the resolution concluded.

The communication, to be forwarded to Commander Stevens' family, was signed by Drs. Herbert W. Fudge, Arthur W. Booth, George R. Murphy, Edward L. Curvish, and Ross G. Loop.

#### Erie County

Dr. Rose Lenahan entertained the Women's Physicians League at dinner at the Hotel Buffalo on November 20. The guest speaker was Dr. Dexter Levy, who discussed "Newer Concepts in Diagnosis and Treatment of Heart Disease."

Among the guests were Drs. Alice Murray, Anna M. Schultz, Anna P. Walsh, Katherine Carnivale, Alta S. Green, Mary Catalano, Thelma Brock, Marion Schierer, Clara March, Agnes McGavin, Lois Plummer, Helen Toskov, and Louise Beamis.\*

"Thiouracil in the Treatment of Thyrotoxicosis" was the subject of an address by Grosvenor W. Bissell, M.D., at the meeting of the Buffalo Academy of Medicine on December 8.

Dr. Bissell, a graduate of the University of Bufialo Medical School, is Research Fellow in Medicine at the Harvard University Medical School.

Discussion which followed the address was by Ivan Hekimian, M.D., Roger Hubbard, Ph.D., David K. Miller, M.D., Walter L. Machemer,

M.D., Alfred H. Noehren, M.D., and Stephen L. Walczak, M.D.

The next stated meeting of the Academy is scheduled for January 12.

#### Essex County

Lt. John F. Spranz of the United States Medical Corps, who has been a patient at the Fletcher General Hospital, Cambridge, Ohio, and who has been retired from the Army, has returned to his home in Au Sable Forks.

Lieutenant Spranz entered active service with the Army on September 17, 1942. During his service he was stationed at the Port of Embarkation in Charleston, South Carolina, in the capacity of port roentgenologist. During the months of February and March, 1943, he was stationed at the Army Medical School, located at the University of Tennessee, Memphis, Tennessee, where he took special study in x-ray and fluoroscopy.

Lt. Spranz is preparing to open his office for the

practice of medicine in the near future.\*

#### Franklin County

The Franklin County Medical Society held its annual meeting on the afternoon of November 18 in the Nurses' Classroom at the Alice Hyde Memorial Hospital.

Dr. George W. Wright, of Saranac Lake, was the main speaker. A business meeting followed his talk, at which the election of officers for the coming

year was held.

Dinner was served at the Elks Club at 6 o'clock. The list of officers will be published in a later issue.\*

Socialized medicine was the theme of an address by Dr. F. F. Finney at the Malone Rotary Club on November 18.\*

#### Greater New York

The thirteenth annual medical-dental convention arranged by the Joint Committee of the Organized Medical and Dental Professions of the City of New York was held at the Hotel Pennsylvania in New York City on December 7 and December 9.

Presiding at the December 7 session were Dr. J. Presiding at the December 7 session were Dr. J. Stanley Kenney, president of the Medical Society of the County of New York, and Dr. Frederick W. Williams, president of the Bronx County Medical Society. The following program was presented on that day: "Pathology of the Oral Cavity in Relation to Systemic Diseases," by Charles F. Geschickter, M.D.; "Dental Infection in Rheumatic Diseases," by Ralph Boots, M.D.; and "Oral Pathology in Relation to Constitutional Diseases," by Andrew A. Egyston, M.D. by Andrew A. Eggston, M.D.

Dr. John J. Gainey, president of the Kings County Medical Society, and Dr. Jacob Werne, president of the Queens County Medical Society, presided at the session held on December 9. There were two scientific addresses on the program: "Effects of Vitamin Deficiencies upon the Oral Mucosa," by Norman Jolliffe, M.D., and "Rheumatic Fever in Its Relation to Dental Disease," by Leo Taran,

Members of the convention committee were: Albert F. R. Andresen, M.D., chairman; G. B. Gilmore, M.D., vice-chairman; Robert M. Fischer, D.D.S., secretary-treasurer; Henry S. Dunning, D.D.S., secretary-treasurer; Henry S. Dunning, M.D., D.D.S.; George H. Dow, M.D.; Robert L. Heinze, D.D.S.; Edward A. Lusterman, D.D.S.; Frederick F. Pfeiffer, D.D.S.; and John F. Wolfram, M.D.

#### Kings County

Only 84 Brooklyn doctors under 38 years of age, out of 5,882 physicians registered in the borough since Pearl Harbor and an estimated 5,100 in practice then, have not applied for commissions in the armed services, according to a survey by the Kings County Medical Society made public on November 6.

Out of these 84, the survey shows, 53 are listed as essential in their civilian practice. Only 31 have refused to apply for commissions or refused

commissions offered them.

Brooklyn had about 2,500 doctors under 38, according to Dr. Charles F. McCarty, secretary of the society's War Participation Committee, which made the survey, so that the 84 who have not applied for military service make up 3.3 per cent of the total, as against 96.7 per cent who have.

Not all who applied obtained commissions, the

survey shows,\*

#### Monroe County

A public mass meeting was held in Rochester on Wednesday, December 15, on the question, "Shall Health Planning Be an Integral Part of a Master

Postwar Plan for a Better Rochester?"

Arrangements were in charge of the Health Education Committee of the Medical Society of the County of Monroe. The main speaker was Dr. W. W. Bauer, director, Bureau of Health Education, American Medical Association. Other features of the program included a health exhibit, health educational film, and a noon meeting of combined service clubs.\*

#### Montgomery County

Dr. Stella Partyka has returned to her native city of Amsterdam, where she has opened an office

for the general practice of medicine.

Dr. Partyka went with her parents to Torrington, Connecticut, in 1916 and there received her early education, having been graduated from Torrington High School at the head of her class. She took a premedical course at the Washington Square College of New York University and was awarded a Bachelor of Science degree. While attending this college she was elected to the Aesclepiad, a woman's national honorary medical society.

She next studied medicine at the Bellevue Medical College in New York City and later continued these studies at the University of Krakow in Poland, where she was awarded the degree of

Doctor of Medicine in 1938.

While in Poland Dr. Partyka served an internship at the Children's Sanatarium, at the health resort in Zaxopane, and at St. Lazarus' Hospital

in Krakow.

Returning to the United States she was intern and later resident physician at the Norwegian Lutheran Deaconess Hospital in Brooklyn for more than two years. From July, 1942, to August, 1943, Dr. Partyka was assistant physician at the Montgomery Sanatorium.\*

#### New York County

At the annual meeting of the county society held on November 22 the following officers were elected for 1944: president-elect, Kirby Dwight; first vice-president, Roy B. Henline; second vice-president, Luther B. MacKenzie; secretary, B. Wallace Hamilton; assistant secretary, Beverly C. Smith; treasurer, Fenwick Beekman; assistant treasurer, John Carroll; censors for three years, Ira Cohen and William B. Rawls; chairman, Committee on Legislation, Horace Ayers; chairman, Committee on Public Relations, John DeP. Currence; chairman, Committee on Medical Economics, Maurice O'Shea; chairman, Committee on Membership, Carl Binger; trustee for five years, J. Stanley Kenney; delegates to the Medical Society of the State of New York, to serve two years: W. P. Anderton, Ralph Barrett, Emily D. Barringer, Fenwick Beekman, Conrad Berens, Harold B. Davidson, Roy B. Henline, Samuel Kauffman, J. Stanley Kenney, William B. Long, Madge McGuinness, Nathan Ratnoff, William B. Rawls.

Algernon B. Reese, M.D., has been chosen secretary for Ophthalmology of the American Academy of Ophthalmology and Otolaryngology for the ensuing year.

At the annual meeting of the Southern Surgical Association in New Orleans, La., December 7-9, Charles Gordon Heyd, M.D., discussed "Voice Disabilities Following Thyroid Surgery."

Willard C. Rappleye, M.D., has been appointed to the Advisory Committee on Education of the National Association for the Prevention of Blindness.

Lt. Joseph Zimmerman, MC, A.U.S., has been appointed chief of neuropsychiatry at an American base hospital in North Africa, according to a recent report in the New York Times.

Dr. William Dock, professor of pathology at Cornell University Medical College since 1940, has been appointed professor of medicine and chairman of the department at the University of Southern California School of Medicine, Los Angeles.

A new national headquarters of the medical division of the War Shipping Administration and the United Seamen's Service has been opened at 107 Washington Street. Dr. Daniel Blain, director of the division, announced that the headquarters will be the administrative center of the national W. S. A.-U. S. S. medical program.\*

Dr. Maria Escobar, Guatemalan physician, is the only woman among seventeen recipients of Latin-American scholarships offered annually by a New York City committee to residents of the neighbor republics, entitling them to a year's study in New York City, plus all their living expenses. These scholarships are sponsored jointly by New York business firms and the Co-ordinator of Inter-American Affairs.

of Inter-American Affairs.
"In my country it is very important to improve the health of children," Dr. Escobar said in an interview the other day at International House, 500 Riverside Drive, where the group is quartered. "I have been studying pediatries at the Post-

Graduate Hospital and have had also a four-week course in children's health work at the Kips Bay-Yorkville Health Center. Now I am taking some courses at Teachers College in child development and care, and I am awaiting an opportunity to do some practical work with children in a big city hospital. It is all a wonderful experience for me."

Dr. Escobar was the only woman in a class of a hundred medical students graduated from the University of Guatemala. In fact, she is Guate-

mala's first woman physician.\*

Dr. Walter Timme, director of the neuro-endocrinology department of the Neurological Institute of New York and professor of clinical neurology at Columbia University College of Physicians and Surgeons, received one of four Townsend Harris medals awarded at the sixty-third annual alumni dinner of City College in the Hotel Roosevelt, November 13. The medals are named after the founder of the college and are awarded annually. Dr. Timme was graduated in the class of 1893. The citation accompanying the award acknowledged Dr. Timme's contributions to the field of endo-crinology, in which he is credited with being a pioneer, and recognized his contribution to the art and science of healing as "teacher, hospital consultant, and specialist in practice."

A one-year grant has been allocated by the Commonwealth Fund to the New York City Mental Hygiene Committee, State Charities Aid Association, to study the psychiatric needs of men dis-charged from or rejected for military service.

The professional staff for the project includes Dr. Sol W. Ginsburg, psychiatrist, Mrs. Rae L. Weisman, and Mrs. Bluma Swerdloff, psychiatric social workers, Ruth Valentine, psychologist, and Mr. and Mrs. Raymond Franzen, research consultants. A study of 500 each of psychiatric rejections and discharges will be made in order that an accurate picture may be obtained for recommendations to fill whatever needs may be determined, especially to find out how many persons in these groups need rehabilitative services which the community does not offer.

#### Ontario County

Dr. Daniel A. Eiseline, of Shortsville, was host to the Canandaigua Medical Society on December 9. Dr. C. Harvey Jewett was reader.\*

#### Orange County

After having served over a year with the U.S. Army Medical Corps, Dr. Meyer Zodikoff has been placed on the inactive list and has resumed his practice in Newburgh.

A captain in the Medical Corps, Dr. Zodikoff returned from North Africa in June and since then has been undergoing medical care. He was placed on the inactive list because of a medical disability.

Metropolitan hospitals in New York before taking up a practice in Newburgh.\*

#### Queens County

Plans for the postwar rehabilitation of Queens-Nassau podiatrists now serving in the armed forces were discussed at the November meeting of the Queens County Podiatry Society.

Approximately twenty-five per cent of the practicing podiatrists in Queens and Nassau counties are now serving in every branch of the armed forces including the maritime service and the Coast Guard. Several podiatrists in the Army were recently assigned to newly established camps for the WAC.
"Regional Anatomy" was the topic of a round-

table discussion which preceded the business

meeting.\*

#### Rensselaer County

The Rensselaer County Medical Society nominated Dr. Richard P. Doody for the presidency at the regular meeting in the Health Center on Novem-

Others on the slate were Dr. John F. Connor, vice-president; Dr. Ranald E. Mussey, secretary; Dr. F. J. Fagan, treasurer; and Dr. Charles H. Sproat and Dr. William Trotter, censors.
Dr. John D. Carroll and Dr. Stephen H. Curtis

were nominated as delegates to the state convention, with Dr. Clement J. Handron and Dr. John Sibbald as alternates.

The group discussed the Wagner-Murray bill and the effect of socialized medicine on all phases of the profession. They also saw a sound movie on peptic ulcer.\*

#### Schenectady County

The annual tuberculin tests given seniors and those participating in competitive athletics was given on November 15 at Nott Terrace High School in Schenectady.

Through the cooperation of the Schenectady County Medical Society, the chamber of commerce health committee, the city health department, and the Schenectady county tuberculosis committee, the improved medical measures for discovery of active tuberculosis or an infection are to be made available, without charge, to pupils in the city's schools.

#### Steuben County

Dr. E. H. Ober, of Painted Post, was named president of the Steuben County Medical Society and Dr. R. J. Shafer, of Corning, was re-elected secretary-treasurer, at a luncheon meeting of the association in Bath on November 11. Dr. Stacy Koenemann, of Avoca, was elected vice-president, an office formerly held by Dr. Ober. The retiring president formerly held by Dr. Ober. is Dr. Stuart H. Bean, of Addison.

Dr. H. B. Smith, of Corning, and Dr. L. M. Kysor, of Hornell, were elected delegates to the State Society convention. Dr. Luther A. Thomas, of Painted Post, and Dr. William Tracy, of Hornell, were chosen alternates. Re-elected to three-year terms as censors of the society were Dr. C. M. Lapp, of Corning, and Dr. A. E. Richmond, of Wayland. Dr. Ober presided in the absence of

Dr. Lapp.
The speaker, Dr. Forrest Young, associate professor of surgery at the University of Rochester School of Medicine and Dentistry, spoke on the early and late treatment of burns. He discussed the use of plasma as a precaution against shock and the use of various sulfa ointments, tannic acid, and saline dressings. His talk was illustrated with lantern slides.\*

#### **Ulster County**

Dr. Frederic W. Holcomb, superintendent of the Ulster County Tuberculosis Hospital, was the

guest speaker at the weekly luncheon of the Kings-

ton Lions Club on November 2.

Dr. Holcomb brought to the attention of the Lions Club the valuable work which the Ulster County Tuberculosis Hospital is performing during wartime in the continuing fight on the disease, revealing definite figures on this disease as they have affected Ulster County residents and the successful fight which is being waged by the modern county institution.

Dr. Holcomb also covered in his address the economic loss to the nation and also to local residents as a result of the continuing effects of tuberculosis. He also dwelt upon the part that the United States Army is playing today in recognizing the carriers of the disease through physical examinations which

are conducted at induction centers.

Dr. Holcomb also made a plea to employers to have sympathetic consideration for tuberculars who are able to take their place in war industry and

other fields.

Following his address, President Baer thanked Dr. Holcomb in behalf of the club and praised his address as one of the finest Kingston Lions Club members have been privileged to hear.—Kingston Freeman

#### Warren County

Dr. Herbert A. Bartholomew, Glens Falls physician and surgeon and a former Warren County coroner, now a lieutenant commander in the United States Naval Reserve, has been elected a Fellow of the American College of Surgeons.

#### Westchester County

After having served a year as a Captain in the Army Medical Corps, Dr. Henry J. Margotta, City Physician of New Rochelle, has been placed on inactive status and resumed his duties as City Physician on November 1. Dr. Margotta served for a while as battalion surgeon with the 11th Armored Division and was later assigned to the staff of La-Garde General Hospital in New Orleans. Dr. Clifford H. Fulton, Examining Physician for the Board of Education, took Dr. Margotta's place during his absence and has now returned to his post with the school system.

Dr. George Hallemann, of Mount Vernon, received his final citizenship papers on September 1, 1943, and is now a citizen of the United States.

#### AVIATOR "BLINDNESS" REPORTED TO DOCTORS

Blindness on one side, which aviators get at high altitudes, was described to the Aero Medical Association of the United States at a recent meeting in Cincinnati.

The cause is not in the eyes but in the brain, owing to some unidentified disturbance in gray matter created by the low pressures of the atmospheres above 30,000 feet.

The blindness and discovery of the brain disturbance were exhibited by the Laboratory of Aviation Medicine, University of Cincinnati, by Drs. M. A. Blenkenhorn, Eugene B. Ferris, George L. Engel, Joseph P. Webb, and John Romano. The lop-sided blindness follows or accompanies the air bends. The flier is aware of a flickering of light, like heat waves, on one side. He is not likely to realize that also he has lost his sight in a sometimes large area on one side. This loss is a danger in flight. It is not permanent, disappearing after he descends.

A uniform technique which is easy to teach, easy to learn, easy to perform . . . a minimum of accessories and containers for blood collecting, plasma preparation, pooling, banking, and dispensing . . . unbroken asepsis through every step—make the Baxter program simple, economical, and safe

## Medicine and the War

#### 1944 War Sessions of the American College of Surgeons

NE-DAY war sessions will be held in twentytwo cities throughout the United States and Canada, in March and April, 1944, under the sponsorship of the American College of Surgeons. According to a statement issued by the College, the cancellation of the 1943 Clinical Congress makes it especially desirable to adopt this means of informing the profession concerning the developments in medicine and in the conditions affecting medical practice and hospital care which have been rapidly occurring under the pressure of wartime events. In the twelve months intervening between the 1943 and 1944 series of meetings, advancements in military medicine are keeping pace with the advancing armies of the United Nations, and the developments in civilian medical research and practice under the spur of the war emergency are proving to be equally notable.

There will be abundant material for an intensely interesting program for each of the 1944 war

meetings

As in the two previous years the College has been assured of the full cooperation of the official war services of the government. Medical service in industry and the work of committees of the medical division of the Medical Research Council will also be prominently featured on the program. The most outstanding benefit of the War Sessions has been the effecting of better mutual understanding between the various government services and the medical profession and the hospitals in gen-

Through the meetings the recruitment of medical officers for the military services has been furthered, while at the same time the necessity of maintaining

adequate medical and hospital service for the civilian sick and injured has been duly emphasized.

The War Sessions are designed for the benefit of physicians and surgeons at large, medical officers of the Army and Navy, residents, interns, medical students, and executive personnel in hospitals, and for Junior Candidates and Fellows of the American College of Surgeons.

Meetings are to take place in Des Moines, Minneapolis, Winnipeg, Chicago, Cincinnati, Detroit, Rochester, Toronto, Montreal, Springfield, Massachusetts, Philadelphia, Baltimore, Charleston, South Carolina, Jackson, Mississippi, San Antonio, Tulsa, Denver, Salt Lake City, Spokane, Vancouver, San Francisco, and Los Angeles.

The programs will include motion pictures, reports by representatives of the armed services and the U.S. Public Health Service, forums, conferences, and

round-tables, and scientific presentations.

The American College of Surgeons is also sponsoring, conjointly with the American College of Physicians and the American Medical Association, a series of wartime graduate medical meetings in various concentration centers where large numbers of medi-cal personnel are on active duty with the military forces. The meetings started in July and will continue through January. The speakers are medical officers of the Army, Navy, and Public Health Service, representatives of the Veterans' Administration, Procurement and Assignment Service, Office of Civilian Defense, War Production Board, War Manpower Commission, and other governmental war agencies, and other national authorities. The meetings are one-day sessions scheduled for twenty-two different cities.

#### Kirk Issues Statement on Penicillin

BECAUSE of numerous requests received by the Army for penicillin, Surg. Gen. Norman T. Kirk of the Army Medical Department explained on November 23 that the War Department "at no on November 23 that the War Department "at no time has either controlled penicillin or received the entire output." The Army's position with regard to penicillin supply is exactly the same as that of the Navy, U.S. Public Health Service, and the Office of Scientific Research and Development, each of which receives a monthly allocation of penicillin from the War Production Board. General Kirk also explained that the penicillin allocated to the also explained that the penicillin allocated to the Army Medical Department is intended for the treatment of military personnel and "none of it can be reallocated or released to civilians."

In November, according to the War Production Board, the Army received 56 per cent of the total supply, the Navy 18 per cent, the U.S. Public Health Service (for the treatment of Coast Guard and Merchant Marine personnel) 2 per cent, the Office of Scientific Research (for civilians) approximately 15 per cent, and the scientific staffs of drug companies the remainder for their own research.

Though production of the drug is steadily increasing, at present none of the agencies, including the military, receive as much as they need. Its distribution among military and naval personnel is deter-mined by the Army, Navy, and the Public Health Service.

Distribution of the part which is allocated to civilians is for clinical research and its assignment is determined by a committee headed by Dr. Chester S. Keefer, Evans Memorial Hospital, Boston. Since the amount of penicillin requested by civilians greatly exceeds the available supply, it has been determined by the Office of Scientific Research and Development that requests by civilians must be made through their doctors, who should communicate with Dr. Kenfor by telephone telegrams of the content of t cate with Dr. Keefer by telephone, telegram, or personal letter, giving complete details of the case so that he may have an adequate basis for his decision. -J.A.M.A.

Someone said that of all the millions of species of living organisms on the earth the two about which most had been written were man himself and—the tubercle bacillus.—F. M. Burnet, M.D., in Biological Aspects of Infectious Disease

Agar-agar, formerly obtained from Japanese and Chinese seaweed and used in the artificial cultivation of bacteria, is now a scarce material; the U.S. Bureau of Fisheries is searching for American agar-producing seaweeds.—Minnesota Medicine

## Hospital News

## Commercial Standard Set for Hospital Sheeting for Mattress Protection\*

AT THE instance of the American Hospital Association, a joint committee of manufacturers of hospital sheeting for mattress protection and a committee of the American Hospital Association adopted a recommended commercial standard for this commodity at a meeting held on March 25, 1943. Those concerned have since accepted and approved the standard as shown herein for promulgation by the U. S. Department of Commerce through the National Bureau of Standards.

The standard became effective for new production

from December 1, 1943. ·

#### Purpose

1. The purpose of this commercial standard is to serve as a guide to producers, distributors, and users of sheeting impervious to moisture, used for the protection of hospital mattresses. It also provides a basis for clear understanding among producers, distributors, and purchasers, and for specifying and guaranteeing the quality of such sheeting.

#### Scope

2. This commercial standard covers requirements and methods of test of fabrics coated on both sides or impregnated with a suitable compound. The requirements include thickness; breaking strength; tearing strength; resistance to oil and disinfectants; resistance to sterilization, accelerated aging, cracking and moisture penetration; and burning rate. The wording of a guarantee statement by the manufacturer is included,

#### General Requirements

3. Fabric. The fabric shall be woven cotton, rayon, or any other suitable synthetic or natural fiber. A substantial close-woven selvage, not less

than 1/3 inch wide, is required.

4. Material and Workmanship.—The finished sheeting shall have a uniformly smooth surface and shall be sufficiently flexible for normal hospital use without cracking or losing its impervious character. It shall not be tacky and shall have no objectionable odor. It shall not contain materials known to have an irritating effect on the skin under the conditions of use. The color may be natural gray-white, or pigmented as desired.

5. Resistance to Mineral Oil.—When tested by pooling for two hours with liquid petrolatum U.S.P. (Par. 17), the sheeting shall show no evidence of softening, tackiness, hardening, peeling, blistering, or any other change that might affect its service-

ability

6. Resistance to Disinfectants.—When a sample of sheeting is tested by pooling for thirty minutes with 70% alcohol, 5% lysol, or 5% phenol solution (Par. 17), it shall show no evidence of softening, tackiness, hardening, peeling, blistering, or other change that might affect its serviceability. Samples that pass visual inspection shall meet the requirement for resistance to cracking (Par. 10). Slight hardening shall not be cause for rejection unless

the sample fails under the test for cracking resistance. (Par. 10).

7. Resistance to Sterilization.—A sample of the sheeting shall not be significantly softer or stiffer than the original, shall not be tacky, and shall show no other changes which might affect its serviceability after being subjected to five sterilizations in steam at 121° C. (Par. 18). Samples that pass visual inspection shall meet the requirement for resistance to cracking (Par. 10).

8. Accelerated Aging.—Sheeting which has been subjected to the compressed oxygen test (Par. 19) shall not be significantly softer or stiffer than the original, shall not be tacky, and shall show no other changes which might adversely affect its service-ability. A few small blisters that may appear during the test shall not be cause for rejection, unless they allow penetration of moisture (Par. 21). Samples

that pass visual inspection shall meet the requirement for resistance to cracking (Par. 10).

9. Water Permeability.—Samples tested in accordance with paragraph 21 shall show no evidence

of moisture penetration.

10. Resistance to Cracking.—When tested in accordance with paragraph 20, before and after the tests for resistance to disinfectants, sterilization and accelerated aging (Pars. 17, 18, and 19), the coating shall not crack at the crease, and shall show no evidence of moisture penetration (Par. 21).

11. Burning Rate.—When tested in accordance with paragraph 22, the time required for the flame to travel a distance of eight inches along the test specimen shall not be less than 75 seconds.

12. Thickness.—The thickness shall not be less

than 0.013 inch.

13. Width and Length.—Sheeting shall be 36 inches, tolerance minus 1 inch, wide and shall be furnished in rolls containing approximately 50 to 60 yards. Rolls shall contain not more than 3 pieces, and no piece shall be less than 6 yards long. The width and length shall be marked on each roll. Other commercial widths may be specified.

14. Breaking Strength (Dry and Wet).—The breaking strength of the finished sheeting shall be not less than 55 pounds in warp and 50 pounds in filling in both wet and dry tests when tested by the

grab method (Par. 16).

15. Tearing Strength.—The tearing strength shall be not less than 3.5 pounds in warp and 3.5 pounds filling when tested by the trapezoid method (Par. 23). If the breaking strength of the sheeting is higher than 55 pounds in both the warp and filling, a tolerance of minus 0.4 pound in tearing strength shall be allowed for each 5 pounds' breaking strength above the minimum of 55 pounds, except that the tearing strength shall not be below 2.0 pounds.

#### Methods of Test

16. Breaking Strength—Grab Method (Dry and Wet).—Breaking-strength tests shall be conducted as described in the latest edition of Woven Textile Fabrics—Testing and Reporting, Commercial Standard CS59.

17. Resistance to Mineral Oil and Disinfectants.—

# of distressing symptoms in

#### CYSTITIS, PYELONEPHRITIS, PROSTATITIS, URETHRITIS

The prompt symptomatic relief provided by Pyridium is extremely gratifying to the patient suffering with distressing urinary symptoms such as painful, urgent, and frequent urination, tenesmus, and irritation of the urogenital mucosa.

Gratifying also is the confidence in the physician and his therapy which is so evident in most patients who have experienced the prompt and effective symptomatic relief provided by Pyridium.

Pyridium is convenient to administer, and may be used safely throughout the course of cystitis, pyelonephritis, prostatitis, and urethritis. The average oral dose is 2 tablets t.i.d.

More than a decade of service in properties in fections

### PYRIDIUM

Phenylaze-elpha-alpha-diamine

Pyridium is the United States Registered Trade-Mark of the Product Manufactured by the Pyridium Corporation

MERCK & CO., Inc. Manufacturing Chemists RAHWAY, N. J.

[Continued from page 92]

A sample of sheeting shall be tested by pooling on it a quantity of the agent to be tested for the required length of time at room temperature, after which it is sponged thoroughly with soap and water, rinsed, and dried on a horizontal ventilated screen at room temperature. The length of time and number of periods of exposure shall be as follows:

Mineral oil: One period, 120 minutes. 70% alcohol: One period, 30 minutes.

5% phenol: Five periods, six hours each, samples to be sponged with soap and water and dried between periods.

5% lysol: Same procedure as for 5% phenol.

Samples that pass visual examination after treatment with disinfectants shall be tested for cracking

(Par. 20).

18. Sterilization.—A piece of sheeting 12 × 12 inches square shall be folded once to give a 12  $\times$  6inch rectangle and then folded at right angles to give a 6 × 6-inch square. If necessary to prevent unfolding during sterilization, a loosely fitting clip or band, or a light weight, may be used. The folded sample shall then be sterilized for 20 minutes at 121 C. in pure, saturated steam, after which it shall be scrubbed thoroughly with soap, water, and a soft brush or sponge to remove any wax, gloom, or finishing materials. Folded as before, it shall then be subjected to four additional sterilizations of 20 minutes each at 121 C. The sheeting shall be removed from the sterilizer and exposed to the air for at least 20 minutes between each two steriliza-After the last sterilization, the sheeting shall be allowed to stand in air for at least 2 hours before examination. Slight surface adhesion, immediately upon removal from the sterilizer, that separates without damage to the coating, shall not be cause for rejection. Samples that pass visual examination shall be tested for cracking (Par. 20).

19. Accelerated Aging.—A specimen shall be enclosed in an oxygen bomb filled with oxygen under a total pressure of 300 = 10 pounds per square inch, and held at a temperature 69 to 71 C. in accordance with method described in Federal Specification ZZ-R-601a, for eight days. Samples that pass visual examination shall be tested for cracking

(Par. 20).

Cracking Resistance.—A piece of sheeting at least 6 inches square shall be folded double and placed on a smooth, hard, flat surface. The folded edge is then rolled 10 times (5 times in each direction) along its full length with a metal roller approximately 1 inch in diameter, under a pressure of approximately 5 pounds.

21. Moisture Penetration.—A sample at least 6 inches square shall be clamped in a suitable device and a circular area four inches in diameter subjected to a hydrostatic pressure of 20 inches of water for 60 minutes. Three samples shall be tested, one taken from the middle section of the sheeting and one near each selvage. Creased samples (Par. 10) shall be so placed that the crease is on a diameter of the circle of fabric under test, and the pressure is directed against the surface of the sheeting that was on the inside of the fold. There shall be no evidence of moisture penetration or dampness on the dry side of the sheeting. See 21a, alternate method.

21a. (Alternate method). Hydrostatic pressure of 25 pounds per square inch shall be applied over an area of 1 square inch for 5 minutes, the test to

be conducted in any convenient way.

22. Burning Rate.—A sample of sheeting 15 inches long and 23/4 inches wide is held in a horizontal position by metal clamps spaced two inches apart, which grip the sample along its lengthwise edges. At a distance of 3½ inches from one end, a pencil line is drawn perpendicular to the lengthwise direction of the specimen. Eight inches from this line, another pencil line is drawn parallel to it. One end of the 15-inch strip is then ignited and the time required for the flame to travel the eight-inch distance between the two parallel lines on the sample is observed.

TearingStrength.—Trapezoid method,

A.S.T.M. Designation D39-39.

#### Guarantee

24. It is recommended that sheeting manufactured in accordance with this commercial standard shall be guaranteed by the manufacturer by the following statement appearing on labels, invoices, contracts, etc:

"This hospital sheeting for mattress protection is guaranteed by (manufacturer) to comply with all the requirements of CS114-43, as issued by the National Bureau of Standards."†

† While the above is the complete standard, it is but an excerpt from a pamphlet entitled "Hospital Sheeting for Mattress Protection, CS114-43," to be issued by the Department of Commerce. This pamphlet, which includes a list of acceptors, brief history of the project, membership of the standing committee, etc., will be available from the Superintendent of Documents, Washington, D.C., as soon after the issuance of the mimeographed edition as is practicable.

#### **Improvements**

Hospital equipment valued at \$10,000, a gift to the United States Naval Hospital in St. Albans, Queens, from the National Council of Jewish Women, was formally received on October 29 by Capt. L. L. Pratt, commandant of the hospital. Mrs. Maurice L. Goldman, of San Francisco, president of the council, made the presentation.

The new equipment, which includes a radio call system, a superficial therapy x-ray machine, three diathermy units, and three ultraviolet ray lamps, was purchased through contributions from the 215

national council sections.\*

Congressman William B. Barry, of Queens County has been advised by the Navy Department that the Secretary of the Navy has approved a project for construction of a crews' library and occupational therapy building at the Naval Hospital, St. Albans, in the amount of \$75,000.\*

Lanham Act grants totaling approximately \$72,115 to increase facilities at Syracuse Memorial Hospital from 271 to 327 beds have received the

approval of President Roosevelt.
Word of the presidential okay was received by
John M. Gallagher, regional director of the Federal Works Agency, from Maj.-Gen. Philip B. Fleming.

Federal Works Administrator.

Miss Mary E. Jenkins, president of the board of trustees of Memorial Hospital, and Miss Miriam Curtis, superintendent, said work on the additional

# two short cuts in URINALYSIS

# Galatest

(DRY REAGENT FOR URINE SUGAR)

Time involved - 30 seconds!

# Acetone Test

Time involved - one minute!

Acetone Test (Denco) and its companion product Galatest (dry reagent for urine sugar) simplify "routine" urinalysis.

Acetone Test (Denco) detects presence or absence of acetone in urine in one minute. Color reaction is identical to that found in the violet ring tests. Trace of acetone turns the powder light lavender—larger amounts to dark purple.

#### THE SAME SIMPLE TECHNIQUE FOR BOTH TESTS

I. A little powder 2. A little urine

Color reaction instantly

A carrying case containing one vial of Acetone Test (Denco) and one vial of Galatest is now available. This is very convenient for the medical bag or for the diabetic patient. The case also contains a medicine dropper and a Galatest color chart. The handy Lit or refills of Acetone Test (Denco) and Galatest are obtainable at all prescription pharmacies and surgical supply houses.

Accepted for advertising in the Journal of the A. M. A.

[Continued from page 941

units will be started as soon as possible with hopes of con pleting the project early next year.

The full cost allotment will be for construction and equipping a one-story addition at the north end of the patients' building to provide storage space; conversion of the solarium on the roof of the administration building to provide 20 children's beds, and conversion of the east solaria on the fourth to ninth floors of the patients' building into six-bed wards to provide 36 adult beds.

Miss Curtis said that, because the construction work will be mainly additions to present facilities, very few vital war materials will be used, a fact

which will expedite priority needs.

The work of closing in porches and roofs to provide additional bed space needed for the increased number of cases will take about four months. Miss Curtis estimated.

This is the second Lanham Act grant for increasing Syracuse hospital facilities, New Syracuse General

Hospital having received a similar grant.\*

Construction of a second floor between the ceiling and floor of the Albany Hospital nurses' gymnasium and dining room was started in November, Dr.

Thomas Hale, Jr., medical director, announced.

The \$32,000 government financed project will create additional locker and rest-room space for students and staff nurses and members of the Nurse Cadet Corps. The first floor will continue to be

used as a dining room and gymnasium.\*

The following item was clipped from the Rock-

away Beach Wave:

"Plastic surgery is being applied to the operating rooms of the Rockaway Beach Hospital, in line with the modernization program recently announced by Nathan Boriskin, it was stated by John L. Farrell, chairman of the 1943 Maintenance and Improvement Campaign.

"Streamlining of this section of the institution was shown by the removal of the ancient skylight in operating room. Through the old skylight the sun poured down its rays, to the discomfiture of surgeons, nurses, and interns. A special ceiling has replaced the obsolete skylight, insuring absolute

sterilization for operating purposes.

"In the minor operating room, where tonsillectomies and similar operations are performed, the walls have been replastered and a new ceiling erected. Plans for the installation of a stainless floor in the minor operating room are under way.

"Outside windows are being reputtied and the sills repainted, so that a freshened appearance will

greet the eye.
"Authorization has been given by the directors for the purchase of up-to-date x-ray equipment, replacing the obsolete equipment now in use. This will require the relocation of the x-ray, physiotherapy, and prenatal service departments. The over-all expenditure for this essential change, it is estimated, will exceed \$10,000. Meanwhile many alterations which will materially assist the personnel in the performance of their service to patients are under wav."

The new 60-bed addition to the DeGraff Memorial Hospital in Tonawanda is scheduled to be completed in December. The entire cost of the new addition and equipment is being paid by the Federal Works Agency of the U.S. Government. The addition will remain the property of the U.S. Government for the duration of the war and for a short period there-

Excavation was started in October for the \$486,000 addition to Deaconess Hospital in Buffalo. scheduled for completion by next July 1. The twostory structure will house 144 beds, a nursery with 60 bassinettes, additional laboratories, and expanded kitchen and dining room space. Facilities for the Nurses' Training School will include a dietetic laboratory, basic science laboratory, and lecture and assembly rooms. The addition will cover a ground area of 332 by 94 feet and will be constructed with federal funds.

New x-ray equipment for Jamestown General Hospital, ordered months ago, probably will be installed by the first of the year, Adolph Beckdahl, chairman, told the Health and Hospital Board after revealing receipt of a WPB promise of the necessary priority.

#### At the Helm

Maj. Nicholas R. Locascio, of Yonkers, chief of medical service and post psychiatrist at the station hospital at Fort Hancock, New Jersey, for the last two and one-half years, has been appointed commanding officer of a psychiatric station hospital at Stormville, New York.

Major Locascio will be the first commanding

officer of his new station, the Green Haven Hospital, recently taken over from New York State by the

Army.

During his period of service at Sandy Hook, Major Locascio, with Col. John P. Beeson, former hospital commanding officer, worked out plans for enlarging and modernizing what formerly was a barracks building into what is now the auxiliary hospital.

The Yonkers physician also played a large part in other improvements in hospital facilities at Fort Hancock and was plans and training officer for the hospital complement.

One of the major jobs assigned him while he was at Fort Hancock was the training of a large number

of Army nurses.

A graduate of Fordham University and Georgetown University Medical School in 1927 and 1931, respectively, Major Locascio in civilian life was associated with hearitals in New York College. ciated with hospitals in New York City in departments of psychiatry.

He had been a reserve officer since 1931, prior to

being placed on active duty.\*

Dr. Malcolm R. Blakeslee, of Shortsville has been re-elected president of the F. F. Thomson Hospital staff physicians. Dr. Frederick C. McClellan con-

Fast administration
—a dose is delivered in 30 seconds

Less disagreeable garlic odor following injection

Well-tolerated — fewer gastre-intestinal upsets — full doses can often be given to patients intolerant to the arsphenamines

No waiting for preparation of the solution—it is immediately soluble in the ampoule

# At Your Service MAPHARSEN

When arsphenamines are taken into the body, it is believed that approximately one-tenth of the amount administered is converted into arsenoxide. To this oxidized product, rather than to arsphenamines themselves, investigators attribute the spirocheticidal action of these drugs. MAPHARSEN\* is meta-amino-para-hydroxyphenyl arsine oxide (arsenoxide) hydrochloride which offers an effective antisyphilitic therapy...a form that causes rapid disappearance of spirochetes and prompt healing of lesions...and one that has facilitated development of the highly-effective, modern types of antisyphilitic treatment.

\*Trade-mark Reg. U. S. Pat. Off.

You can now readily obtain supplies of Mapharsen Ampoules for use in your practice. Increased manufacturing facilities have made it possible for us to materially increase our output, and to maintain more adequate supplies in drug stores throughout the country.

Parke, Davis & Company, Detroit, Michigan

[Continued from page 96]

tinues as vice-president and Dr. E. C. Merrill was named secretary and treasurer.\*

Dr. Ina C. Hall, who has been superintendent of the Brooks Memorial Hospital in Dunkirk since May of this year, resigned on December 1.\*

Frederick G. Bascom was re-elected president of the Glens Falls Hospital Board of Directors at the annual meeting on November 1. Other officers, all re-elected, are: William H. Barber, vice-president; Frederick B. Richards, secretary-treasurer; Miss Flora E. Bent, clerk.

Members re-elected to the board were H. F. Bullard, Dr. W. H. Ordway, Mr. Richards, Harry

H. Singleton, and Miss Bertha Wilmarth.\*

Due to ill health, Sister Julienna of the staff of St. Anthony's Hospital in Queens, has been relieved of her duties as Superintendent, and Sister Alphonsia has been appointed Superintendent in her stead. We wish her every success. Sister Bonaventure has been acting superintendent.

Dr. Carl S. Tomkins has been elected president of the Batavia Hospital staff. He succeeds Dr. L. F. Quinlan.\*

Dr. Ansell W. Derrick, of Charlotteville, Virginia, has assumed his duties as director of the city laboratory in Kingston, to fill the vacancy caused by the resignation of Dr. J. S. Taylor, who is now pathologist at Vassar Brothers Hospital, Poughkeepsic.

Before going to Kingston, Dr. Derrick was associate professor of pathology at the University of Virginia in Charlotteville. He received his medical degree from the Medical School of the University of Virginia.

He has made a special study of cancer and allied diseases, and will carry on the laboratory program which was inaugurated with great success by Dr. Taylor.\*

Dr. Harry A. LaBurt, for twenty years in the New York State Department of Mental Hygiene, has been named superintendent of Creedmoor State Hospital in Queens. Dr. LaBurt has been at Creedmoor as acting superintendent since shortly after Dr. George Mills resigned from the post last spring while the institution was under investigation.

Dr. LaBurt, who entered the State Department as a deputy medical director in 1924 after graduating from the University of Buffalo Medical School, was most recently superintendent of the Harlem Valley

State Hospital.

Dr. Isadore Rees, of New York City, assistant superintendent of the Bronx Hospital and formerly national chairman of the B'nai B'rith committee on scouting, has been appointed executive secretary of the Leo N. Levi Memorial Hospital in Hot Springs, Arkansas.

Dr. Vladimir Podryski, member of the medical staff of the Veterans' Facility in Bath for more than a year, has left for a new post in the Bronx Veterans' Hospital.\*

Dr. James V. Murphy has been appointed child welfare and parochial school physician in Niagam Falls, to succeed Dr. Francis F. Talbot, who re-signed, on October 16.\*

Dr. William R. Carson, for the past twelve years associated with the medical staff at the State Hospital, Ogdensburg, recently began his duties in charge of x-ray work at Potsdam Hospital, succeeding the late Dr. Robert J. Reynolds.

Dr. Carson, following his graduation from Tufts Medical College, Boston, interned for two years in Brooklyn and later accepted a hospital residency in Boston. He came from Boston twelve years ago to Ogdensburg, where he served at the State Hospital and was also associated with the Hepburn Hospital

Mrs. Jennie Carson, wife of Dr. Carson, is also a physician, serving in Kings County Hospital, She plans to come to Potsdam with her Brooklyn.

husband during the coming year.\*

Edward S. Graney, steward of Binghamton State Hospital, completed on November 2 fifty years of service at the hospital where he started as a stenographer in 1893. He became bookkeeper in 1898 and steward in 1909. During this long term of service Mr. Graney has handled the business affairs and the farm of the hospital. He is a member of the Committee of Stewards Conferences and also of the Committee on Statistics and Forms of the New York State Department of Mental Hygiene.

Dr. Stephen Major, formerly of Boston, has been appointed to the staff of Binghamton State Hospital. Dr. Major was graduated from the Royal University of Milan, Italy, in 1931, and has just completed a residency in Boston City Hospital.

Appointment of Dr. Newton J. T. Bigelow, superintendent of Edgewood State Hospital, Suffolk County, as assistant state commissioner of mental hygiene was announced in November by Dr. Frederick MacCurdy, commissioner.

Dr. Bigelow succeeds Dr. H. Beckett Lang, who is on leave of absence with the Navy, in which he is a

lieutenant-commander.

The new assistant commissioner, a native of Canada, was first assistant physician at Pilgrim State Hospital and director of clinical psychiatry at Utica State Hospital at Edgewood.\*

Dr. Edward I. Salisbury, of Flower Hill, has been appointed medical director of the United Fruit Co.\*

#### Newsy Notes

Mrs. T. J. Grimaldi, nurse at Nassau Hospital, in Mineola, and supervisor of clinical instruction for members of the Volunteer Male Attendants Association, was presented with a scroll by the twenty-one members of the first graduating class of the association, who finished their work the last week in October. The scroll expressed the gratitude of class members for her work in the male attendants' school.

The classes are held at Nassau Hospital. They are open to any volunteer who wishes to give his services in the various hospitals. The members of the first class have already served in the North Country Community, Nassau, Mercy, South Shore Communities, and the Meadowbrook Hospitals.

There is a great need for volunteers for this work.\*

Dr. Katherine Whitin Swift and Dr. Thomas Pattison Almy, both of the New York Hospital in New York City, were married on November 12.\*

A ten-car hospital train, the first of many being built in the United States for use in combat zones overseas, was on exhibition in the Pennsylvania Railroad station in Jersey City, New Jersey, on November 23.

The train will go to Philadelphia and other cities on the way to the California-Arizona maneuver area, where it will be used temporarily for training pur-

Nown as "The Third Hospital Train," the train is a complete unit in itself, carrying, in addition to the most modern surgical equipment, generators and boilers to supply heat, electricity, hot water, ventilation, and refrigeration. Each car is equipped

When these trains reach combat areas they will replace the foreign-made cars used to carry wounded American soldiers from the evacuation points just behind the battle lines to general hospitals. To do this the hospital train will move up to within twenty-five miles of the actual fighting zone.

with fluorescent lighting.

Built specifically for overseas duty, where the railroads have many sharp turns, narrow bridges, low tunnels, and bad roadbeds, the hospital cars are considerably smaller than the average American railroad cars. They are only forty feet long, about half the length of Pullmans, and several feet nar-

The ten steel cars consist of six ward cars, each capable of accommodating sixteen bed patients or a larger number of sitting patients, a kitchen car, two personnel cars for officers and enlisted men, and the utilities car where the generators and boilers are housed. The train is painted the familiar Army olive drab and hospital and Red Cross markings are displayed on the exterior of each car.\*

With plans for a postwar expansion program almost complete, Mercy Hospital in Buffalo has opened an appeal for funds to carry out the project. The appeal is being made in letter form to members of the nurses' alumnae, friends, and former patients of the institution.\*

The Albany Times-Union recently published a series of six articles on "Hospital Problems Today," in which were discussed the critical nurse shortage, the special-nurse shortage, volunteer aides, the shortage of general personnel and supplies, and hospital finances. These articles attracted much attention and the Times-Union published a number of letters received in reply to them.

Another group of boys and girls from the Utica area will go to the Shriners' hospital for crippled children in Springfield, Massachusetts, as a result of a clinic conducted on November 6.

Though the clinic was an entrance examination for 10 patients, it constituted graduation exercises for some who had outgrown all symptoms of paralysis or limb injuries. Others temporarily released will return for further treatment.

The children came from Syracuse, Utica, Rome, Oncida, Ilion, Frankfort, Mohawk, Sauquoit, Norwich, Camden, Westmoreland, and Boonville. In spite of their disabilities, they were a cheerful lot, eating cookies and lollipops while they waited to be called to the examination room. There Dr. Garry deN. Hough, chief surgeon of the Springfield institution, examined the afflicted legs and arms, rapidly dictating symptoms and recommendations to his secretary between scraps of leisurely small talk with his juvenile patients.—Utica Observer-Dispatch

The Samaritan Hospital in Troy is given a legacy of \$325,000 for the maintenance of the James A. Eddy Memorial Foundation at that institution under the will of Mrs. Elizabeth H. S. Eddy, who died on October 30.

The James A. Eddy Memorial Foundation was established at the Samaritan Hospital in 1928 by Mrs. Eddy, for the care of persons suffering from incurable disease or from what may at the time be deemed to be incurable disease; of persons suffering from chronic though curable disease who are permanently physically incapacitated but who still need medical or surgical treatment.\*

Hundreds of Brooklyn and Long Island high school students recently visited hospitals in the area as part of the current recruiting campaign of the Nursing Council for War Service on Long Island. Open-house week was observed by twentythree hospitals.

Tickets were distributed to 132 high schools for the campaign, which was held to focus the interest of high school seniors on the immediate war contribution they can make by becoming student nurses.\*

A campaign to raise funds to purchase five thousand potted plants to be placed at the bedsides of hospitalized service men and women and five thousand Christmas trees for as many wards in military hospitals in the New York area was begun on November 10 by the Metropolitan Area Hospital [Continued on page 102]

# "How much do you smoke?"

# is only part of the question!

Far more important than "How many cigarettes do you smoke?" may be the question, "How irritating is your cigarette?"

RECOGNIZED LABORATORY TESTS\*
SHOWED THAT THE IRRITANT QUALITY
IN THE SMOKE OF FOUR OTHER LEADING
BRANDS AVERAGED MORE THAN THREE
TIMES THE STRIKINGLY CONTRASTED
PHILIP MORRIS.

The possibility of irritation from smoking can be minimized by suggesting a change to PHILIP MORRIS.

# PHILIP MORRIS

Service's Committee, which has its headquarters in the 13th Regiment Armory, New York Guard, Brooklyn.\*

South Nassau Communities Hospital, in Rockville Centre, celebrated its fifteenth anniversary on November 20, with a reception and tea at which members of the official staff, board of directors and leaders of the hospital auxiliaries greeted visitors and friends.\*

A blood bank containing sufficient plasma to meet any emergency and to be made available to all those living and working in the community, is being planned for the North Country Community Hospital in Glen Cove, P. Erskine Wood, president of the board of directors of the hospital, announced. It is hoped to have a bank of 50 units.\*

Plans are under way for a 30-room maternity wing for the Champlain Valley Hospital in Platts-Generous contributions have been promised toward the project, which will cost an estimated \$150,000. Dr. E. W. Sartwell, of Peru, recently contributed \$200.\*

The national award of the National Hospital Association for the best educational program of a hospital in a city of 100,000 or more population in the United States was presented to Wyckoff Heights Hospital in Brooklyn on November 16. Wyckoff Heights Hospital won the award at the recent convention of the National Hospital Association.

The award is a plaque, suitably inscribed. Herman Ringe, president of the hospital board, and Louis Schenkweiler, superintendent of the hospital, ac-

cepted the award.

The presentation was made by John H. Hayes, trustee of the National Hospital Association. Hayes also spoke on behalf of the Greater New York Hospital Association, of which he is president. He is superintendent of Lenox Hill Hospital, Man-The New York State Hospital Association was represented by John H. Olsen, chairman of its public education committee. He is superintendent of Richmond Memorial Hospital, Staten Island.\*

The White Plains Hospital Association commem-

orated the fiftieth anniversary of the granting of its charter on Sunday, November 21.

Alexander C. Nagle, president of the board of governors of the Hospital Association, with the Hospital Association, with the other governors was at home to the residents of the community which the Hospital serves, from three to six o'clock at the

Refreshments were served in the Hospitality Center under the direction of Mrs. Arthur W. Mc-Cain, chairman of the Scarsdale Women's Auxiliary,

which sponsors the shop.

For the first time since the opening of the new Hospital building in December, 1939, visitors were permitted to inspect the operating suite. Other

exhibits included the section devoted to the care of Norwegian merchant seamen; a nursing school demonstration of the care of pneumonia fifty years ago and now; the patients' library, which is conducted under the chairmanship of Mrs. John K. Starkweather; the x-ray department; and an exhibit of the Westchester Cancer Committee.

On Sunday morning, the Hospital's Charter Day was observed in many of the churches of Scars-

dale and White Plains.

A "family" dinner was given at the Roger Smith Hotel for the board of governors and the medical staff of the Hospital. Mr. Nagle presided as toastmaster; and Dr. Alan Gregg, director of the division of medical education of the Rockefeller Foundation, spoke on "Medicine Fifty Years Hence."

In connection with the anniversary, the board of governors is publishing a "Report to the Community," a booklet which traces the Hospital through the years, since the time fifty years ago when it had four beds and served a community of five thousand, until the present day when, with 202 beds, it serves a community of some hundred thousand persons living in central Westchester County.

The first record of Scarsdale participation in Hospital affairs was in 1912, when a committee headed by Frank B. Nairne raised \$120 from thirteen residents of the village to help meet an emergency. Scarsdale now contributes approximately \$8,000 annually through the Community Fund and some 190 individual members of the White Plains Hospital Association.—Scarsdale Inquirer

Employees of New York City hospitals purchased over \$353,000 worth of War Savings Bonds during the Third War Loan drive, it was reported by Dr. Edward M. Bernecker, commissioner of the Department of Hospitals.

Dr. Bernecker's report, submitted to the War Finance Committee for New York State, embraced the bond-buying activities of twenty-seven city hospitals. Greenpoint Hospital, in Brooklyn, with almost 75 per cent of its four hundred and twenty employees participating, subscribed to the highest total, more than \$63,000.

Bond purchases in the recently completed drive exceeded those of the Second War Loan campaign by \$201,000, Dr. Bernecker stated. He also reported that monthly payroll saving purchases at the hospitals now "average about \$60,000."

The money will be earmarked for the purchase of three ambulance planes. The funds raised in the second War Loan financed the purchase of a fighter plane, which was christened "The Hypo."

The Queensboro Tuberculosis and Health Association, working in cooperation with St. Anthony's Hospital, Woodhaven, has established a social service department at the hospital for specialized case work with tuberculosis patients. Molly Marshall, medical social worker, is in charge.

The new department will provide patients with consultation services on economic, health, and family problems. Under Miss Marshall's direction a series of weekly health programs, including sound movies and speakers on subjects such as rehabilitation, nutrition, and dental health, has been inaugurated.—Better Times

The State has leased a group of three connecting buildings at Pilgrim State Hospital, in Brentwood, to the Army to be used during the period of the war as a general hospital for the treatment of soldiers. The normal capacity of the three buildings is 1.528 but it is believed that several hundred additional patients might be accommodated therein.

Human milk "banks" are to be established at the Arnot-Ogden and St. Joseph's Hospitals in Elmira.

The contribution of human milk to the banks is in no way inferior to the donation of blood, medical men declared. The process of storing frozen human milk is fundamentally the same as the frozen stor-

age of any food.

The availability of breast milk in Elmira hospitals has, in the past, determined whether some premature frail newborns have survived. Heretofore, when the mother has been unable to provide milk for a critical case, the odds have been against any available supply from other mothers. On the other hand, there are times in the maternity wards when a superabundance of milk is drawn from mothers, only to be discarded because there are no infants needing the excess at that time.

From now on there will be no discarding of precious breast milk. It will be stored perfectly in a frozen state to be on hand when the need occurs.

Elmira pediatricians were assisted by Garth A. Shoemaker, manager of the Hygiea Refrigerating and Ice Cream Co., in arranging for the milk storage.—Elmira Advertiser

The White Plains Hospital and Dr. Edwin G. Ramsdell, its chief of staff, are principal legatees in the will of the late Clarion B. Winslow, of White Plains.

The White Plains Hospital, to which he had contributed more than \$500,000 in recent years, received 6,000 shares of stock, worth \$228,000; part of Mr. Winslow's large library; and one-third of his residuary estate.\*

Free hospital service for needy girls, regardless of creed or color, is to be established in St. Mary's Hospital under terms of the will of the late Zetta O'Connell, of Rochester.

Upon termination of trust fund commitments, the remainder of the estate is to be used to set up a

Zetta O'Connell Memorial Fund, the income from which is to be used "to provide bed or beds, or medical or surgical service and nursing care" for needy girls, of any color or creed, at St. Mary's Hospital.\*

On October 30 formal dedication ceremonies were held at Utica at Rhoads General Hospital.

Present at the ceremony were several Army officers including Maj. Gen. Thomas A. Terry, Commanding General of the Second Service Command. Senator James M. Mead, of New York, delivered the dedicatory address.\*

Physicians in Batavia recently gave a mighty boost to St. Jerome Hospital Building Fund. Bonds of \$1000 were given by Drs. Ward. B. Man-Graney, I. A. Cole, L. F. Quinlan, C. C. Koester, and Paul P. Welsh. Bonds for \$500 have been received from Drs. Frank R. Hall, S. J. Gerace, Bernard Puglisi, and Ralph Stanbury. The St. Jerome's Nurses' Alumnae sent \$200 in bonds.\*

St. Joseph's Hospital for Consumptives, in the Bronx, has changed its name to St. Joseph's Hospital for Chest Diseases.

Because of shortage of doctors and nurses due to those accepting Army and Navy service the County Department of Public Welfare is considering closing the 25-bed children's tuberculosis building at Grasslands and allocating a number of beds for children in one of the wards of the adult tuberculosis wing, it was reported.

The announcement did not come from Welfare Commissioner Ruth Taylor but from Dr. Robert E. Plunkett, State General Superintendent of Tuberculosis Hospitals, reporting on a recent inspec-

tion of the Grasslands institutions.

The children's tuberculosis building at Grasslands, "Sunshine Cottage," was opened in September, 1931, and has long been considered as providing one of the most advanced methods of treating of tuber-culosis among children. Dr. William G. Childress is the physician in charge of both adult and children's tuberculosis wards.

The inspection report shows that during 1942 there were 578 adult patients and 23 children treated in the tuberculosis division of Grasslands.—North

Tarrytown Ledger

### SOCIAL HYGIENE DAY

According to Social Hygiene News, monthly publication of the American Social Hygiene Association, "Social Hygiene Day" for 1944 will be observed on February 2.

The eradication of venereal disease and the promotion of social protection services will be stressed in the programs to be given throughout the country.

The potentiation of the central action of phenobathical by the belladonna alkaloids (Friedberg, Arch f. exp P & P. CLX, 276) renders possible attainment of desired effects with relatively small doses, thus avoiding hang over 'and other unpleasant side actions. In contrast to galenical preparations of belladonna, such as the tincture, Belbarb has always the same proportion of the alkaloids.

Indicationa: Neuroses, migraine, functional digestive and circulatory disturbances, vomiting of pregnancy, menopausal disturbances, hypertension, etc.

Formule: Each tablet contains 1/4 grain phenobarbital and the three chief alkaloids, equivalent approximately to 9 minims of tincture of belladonna.

Belbarb No 2 has the same alkaloidal content but 1/2 grain phenobarbital per tablet.

### DR. JOHN SAPPINGTON—QUININE'S CHAMPION

Just 100 years ago, according to Alden E. Calkins in the Saturday Home Journal of the Journal-Ameri-can, the great-great-grandfather of Ginger Rogers loaded his two flint-lock pistols, packed his saddle-bags with little white pills and set out to stamp the fevers and chills then strangling frontier life in the Louisiana Purchase area.

In the face of bitter condemnation by his colleagues who insisted that the drug was dangerous and that only bleeding and purging cured malaria, Dr. John Sappington had the foresight and courage

to prescribe quinine
"Few persons," says the author, "even in the now
healthy Mississippi and Missouri river valleys where he worked his magic, know what Doc Sappington did when he gave quinine in steady but small doses. This rank heresay outlived its sponsor for most of the last century, but today medical science knows that quinine does the job, and smaller doses of it are more

effective than large ones. Sappington's conservation of a drug that was as scarce 100 years ago as it is now (with no thanks to the Japs) helps more of our fighters get their share of quinine than if that frontier physician had never lived and fought for his principles. .

"Adding high pressure salesmanship to independence, this pioneer in medical life, liberty and pursuit of happiness even had the frontier village

made up of licorice, myrrh, sassafras, and a grain of quinine.

DOCTOR WANTED: A comment in the New York Times-"The human family at the moment is a sick family; so sick that some of its members will be in the convalescent stage for a long time to come, with all that that means in feedleness and flightiness and despondency. They will need a lot of resting, special feeding, patient understanding. They may have relapses. It may be long before they can stand alone: a few may have to learn to walk again. The rest of the family, those that were strong enough at the crisis to throw off the affliction and recover quickly, will have to give up some of their good times and stand by. If they do that-and by all signs they will-the family will surely make a fine comeback and be healthier than ever before. You can't keep a good family down.

But, where is the "doctor?"

### THAT'S A LOT OF STEEL!

Fifteen thousand tons of steel are used in this country for manufacturing auto license plates, reports a Pennsylvania "economist." In his State, alone, the 1,100 tons used for this purpose is sufficient to equip 220,000 soldiers with rifles.

So to save all this metal, the man-Harry M. Parmley, suggests the elimination of plates entirely. As a substitute, a permanent identification number can be painted or otherwise placed on the front or rear of a truck or pleasure car-practically what the railroad companies have been doing on rolling stock for years.

Stickers on the windshield could indicate that State license fees have been paid. Such stickers are now used in fifteen States to permit the legal retention of old license plates.

Now let someone figure out how to salvage the "tin" that is used to make the vehicle that carries the license plate.

#### BIOTIN FOR GROWTH

The most recent of the vitamin B factors to "attain its majority" is Biotin. It is now established that this factor stimulates growth.

But the most remarkable thing about it is that this vitamin can be stored up in pickled foods. As it is easily extracted from foods by acids, vinegar which is used in pickling acts as the medium that extracts the Biotin. In Europe where peasants pickle both animal and vegetable products on a large scale, they get their Biotin even when they must rely almost entirely on pickled foods.

Richest sources of the vitamin factor are: kidneys, brewer's yeast, soybeans, spinach and toma-It is found in the body tissues and in excretions.

Rats in a test, were fed on raw egg-white with the result that they died, for the avidin content of eggwhite checks growth and prevents the biotin from doing its work.

### SUBSTITUTES MAKING GOOD

A dramatic display of products created to save precious materials by conservation, substitution, and simplification has been staged in Washington. Over a thousand articles exhibited show streamlined designs that save thousands of tons of steel, copper, aluminum, rubber, and such vital war materials.

Most of the articles were created to meet strictly military needs, but many of them will interest the noncombatant civilian. Some have been made especially for civilians to release essential material to

the armed forces.

Included among the things shown were—a crib made entirely of wood (instead of metal) with springs using only half the normal amount of steel. . . a door-mat or garden pad made of discarded scraps of wood . . . a series of clear glass fixtures for garden hoses with modernistic hoses in supple plastic to save rubber. . . a watertight flashlight that can be dropped into deep water and still operate. . . a whole ensemble of ceramic kitchen ware and a hot-water heater which substitutes for pre-war metal models. . steel locks and bolts coated with a durable black enamel, to save brass...a concrete bathtub...and a chemical that makes ordinary wood completely fireproof.

### THE WAR PHENOMENON

The war phenomenon is still the change in birth

In Great Britain where a declining birth rate was the most serious problem for the past three decades, a change for the better has now taken place in their fourth year of war.

Recent figures published by the Registrar General's office revealed that there were 180,691 live births in the second quarter of this year—a rate of 17.5 per 1,000 of the population as compared with 16.2 during the same period last year and an average rate of 15.7 for the preceding five years.

Population experts find little comfort in these latest statistics, however, arguing that the recent rise is due to younger marriages and to the emotional strains of a long-drawn-out war. Government authorities and other students point out that since 1923 the annual birth rate has been insufficient to maintain stationary population.

The concern in Great Britain now is how this alarming trend can be permanently arrested. It is believed that the following three points of attack are

essential:

1. Education of the public in order that motherhood may be raised to the status of an honored profession.

2. Relief from the economic burden by child allowances as advocated in the Beveridge report.

3. Better housing, nutrition, education, and programs of public health.

### COT-TAR PIX-LITHANTHRACIS 5%

Therapeutically active in exudative and chronic eczema particularly suitable in children's eczema. • Forms a flexible non-peeling

Can be removed with water

or cleansing creams. Avoids staining of linen. • Causes no untoward irrita-

### EXIT—THE STORK

The old story about the stork is about to disappear in Great Britain. That is—if the local school heads see eye-to-eye with the Board of Education. It seems that simple, sensible answers to childhood questions about sex are preferred and recommended in a pamphlet issued for use in a new course for teachers, leaders of youth groups, and ultimately in parent-teachers meetings throughout the country.

This news parallels the issuance of a new pamphlet here by the Child Study Association of America— "When Children Ask About Sex," in which the editors have attempted in sixteen pages to bring the subject out of language obscurity through which parents have been groping, to come to the point and to convey a great deal of helpful information. (Single copies cost 20 cents, and may be obtained from the Association, 221 W. 57th Street, New York

19, N. Y.)

The pamphlet covers both sides of the matter telling too little and telling too much,-but the authors caution that the pamphlet does not supply a ready answer for ever question a child might ask about sex, or suggestions to be memorized word for

## IN WHOOPING COUGH

ELIXIR BROMAURATE IS A UNIQUE REMEDY OF UNIQUE MERIT

Cuts short the period of the illness, relieves the distressing cough and gives the child rest and sleep. Also valuable in other PERSISTENT COUGHS and in BRONCHITIS and BRONCHIAL ASTHMA. In four-ounce original bottles. A tempoonful every 3 or 4 hours.

gold Pharmacal Co., New York

### PISTOL-PACKIN' NURSES

Through one of science's latest achievements in this war, Navy nurses are now a kind of "pistol packin' mama."

The pistols they have been equipped with are per haps a forerunner of a future ray pistol such as Buc Rogers of the funnies uses in his inter-planetary flights. Designed for healing, they are electric and air-cooled, and shoot ultra-violet rays.

Actually, the pistols are miniature ultraviole ray lamps for use in treating slow-healing wounds abscesses, ulcers and certain skin diseases. In spite of their tiny size, the pistol lamps will redden the skin in one minute.

The burner is a transparent quartz tube in which the source of the rays is contained. The entire "apparatus" measures but three inches in diameter and only ten and one-half inches long.

### "A PLACE FOR EVERY TOE AND EVERY TOE IN PLACE"

... a fundamental rule for any footwear construction.

But an orthopedic shoe must be built for more than that in order to prevent or correct foot troubles and deformities. It must follow the pattern of nature as closely as possible to permit proper position and action of every bone and muscle—to allow perfect circulation, correct joint articulation and help strengthen sustaining muscles. It must shift the weight of the body from the arches to the proper "weight-bearing" surfaces and help the doctor's own treatments.

Whether the need is preventive or therapeutic, you will find the right qualities in Pediforme shoes. Many years of continuous service to members of the medical profession authenticates that point.

A SHOE FOR EVERY MEMBER OF THE FAMILY...A SHOE FOR EVERY INDIVIDUAL REQUIREMENT.

bacteriostatic treatment of burns with . . .

## Sulfadiazine Lederle

B ACTERIOSTASIS is essential for healing in extensively burned areas. This may be achieved by appropriate surgical and medical measures adopted immediately after the injury is received. The most important bacteriostatic measure is the use of sulfonamides

SULFADIAZINE Lederle may be employed locally in the form of "SULFADIAZINE IN ETHAN-OLAMINES SOLUTION (PICKRELL) Lederle," or "SULFADIAZINE OINTMENT Lederle."

SULFADIAZINE UNIMENT Leaerte.

SULFADIAZINE Lederle may be given by mouth if drug blood levels remain insufficient to inhibit bacterial growth. Caution should be observed in the simultaneous use of oral and local therapy since excessive drug blood levels may result. Maintenance of urinary output between 1,000 and 1,500 cc. daily and an alkaline 'urine are advisable during intensive Sulfadiazine therapy.

#### PACHAGES

## Just as expert servicing keeps your car running smoothly

... so G-E's P. I. and A. Service

## keeps fine x-ray equipment operating at top efficiency

Always, your investment in fine equipment is fully justified by the better and more satisfactory service it gives you.

And the greater your investment, and the finer your equipment, the more important it is that you protect it with proper use and care. If neglected, lowered efficiency is inevitable, and eventually costly repairs.

General Electric's *Periodic Inspection and Adjustment* service precludes breakdown of x-ray apparatus from neglect, because at specified intervals a specially trained service engineer gives it the attention essential to proper maintenance. It's a type of service which hundreds of x-ray laboratories deem indispensable—many of them have been renewing their *P. I. and A.* contracts every year for 13 years.

Through G. E.'s branch offices located in every section of the country, *P. I. and A.* service is readily available. The G-E representative in your vicinity will be glad to give you full particulars. You'll find him a reliable source of helpful technical information.

J. Urol. 49 2 (Feb.) 1943

### PACKAGES

Sulfadiazine Tablets for Oral Use Bottles of 50, 100 and 1000 tablets, 0.5 Gm. (7.7 grains) each.

Sodium Sulfadiazine Solution Parenteral 25% Sets of 6 and 25 ampuls (10 cc. each).

Sulfadiazine, like other instruments of precision, must be employed properly to achieve optimal results. Recently the work of Gilligan, Garb and Plummer¹ has indicated how the crystalluria and hematuria occasionally observed following sulfadiazine may be obviated. The curves of solubility of sulfadiazine and acetyl sulfadiazine in urine rise steeply as the pH is increased above neutrality. Thus the maintenance of an alkaline urine, together with a urinary output of 1,000 to 1,500 cc. or more per day, would be likely to diminish sulfadiazine crystalluria and resultant irritation of the genito-urinary tract.

Gilligan, Garb, Wheeler and Plummer<sup>2</sup> have found that alkali therapy sufficient to maintain the urine neutral or slightly alkaline (about 16 Gm. of sodium bicarbonate daily, unless contraindicated) was not only advisable but that renal damage and urinary tract obstruction, consequent upon precipitation of sulfadiazine and acetylated sulfadiazine, were preventable.

The wide usage of sulfadiazine, for both therapeutic and prophylactic purposes, is the best evidence of its relative lack of toxicity. Recently there has appeared a significant article by Kuhns, Nelson, Feldman and Kuhn³ who employed sulfadiazine prophylactically in more than 15,000 soldiers with not only a resultant reduced incidence of infection (meningitis) as compared with controls, but also without serious toxic effects.

MYOCARDIAL STIMULANT AND POWERFUL DIURETIC. EFFECTIVE IN BRONCHIAL ASTHMA, PAROXYSMAL DYSPNEA AND CHEYNE-STOKES RESPIRATION.

Numerous reports in the literature comment on Prompt Relief Favorable Action, and Dramatic Improvement in these conditions

H. E. DUBIN LABORATORIES, 250 East 43rd Street, New York, N. Y.

## PRIODAX

## DEFORE THE TEXTBOOK PICTURE DEVELOPS

Today the physician seldom sees a typical textbook case of fully developed B Complex deficiency.

On the other hand, there are thousands of patients who are partially lacking in these essential vitamin factors—patients in whom optimum improvement is noted only when replacement therapy with Whole Natural Vitamin B Complex is instituted.

The clinical demand for an easily administered source of Whole Natural Vitamin B Complex in concentrated form furnished the spark for research which led to the development of **BEZON**.

BEZON\* is Whole Natural Vitamin B

Complex—concentrated to high potency from natural sources—no synthetic vitamin factors are added.

- ★ Whole B Complex is important because B deficiencies in man are almost always multiple—a diet poor in one factor of the B Complex is apt to be lacking in other factors.
- \* Natural B Complex is important because only in Whole Natural Vitamin B Complex can all 22 vitamin B factors be obtained.

**BEZON** is made only in the distinctive two-color gelatin capsule. Supplied in bottles of 30 and 100 capsules.

Samples and literature available on request

AVAILABLE IN various potencies with or without Phenobarbitol. Literature on request.

The ORIGINAL ENTERIC-COATED TABLET OF THEOBROMINE SODIUM ACETATE

to control frequency and severity of attacks in CARDIOVASCULAR AND RENAL DISEASES and to prevent EDEMA

Clinical experience and studies have proven the value of Theobromine Sodium Acetate in certain Cardiovascular and Renal Diseases. In Angina Pectoris, used adequately, it permits more work by the individual without developing precordial pain or distress. As one of the most effective Xanthine Vasadilators it helps increase the available blood supply to the heart and kidneys to increase the efficiency of these organs.

It has also been found an effective aid in treating and preventing Edema of Cardiac or Renal origin. The enteric coating (especially developed for Thesodate) permits larger doses without the drug's contact with the Gastric Mucosa.

## Carnacton of clinical value

In ANGINA PECTORIS . ARTERIOSCLEROSIS . PERIPHERAL VASCULAR DISEASES

Carnacton is a biologically tested extract of highly vascularized and active diaphragmatic muscle with a high metabolic rate... providing dependable vasodilator and depressor benefits. Carnacton helps establish collateral circulation and promotes cardiovascular tone and vitality.

Ampuls of 1 cc. and 2 cc.-boxes of 12 and 50; vials of 30 cc. for oral use. For detailed brochure address Dept. N.

CAVENDISH PHARMACEUTICAL CORP., 25 West Broadway, New York

### The Importance of Having

### \*ELIXIR BEPADIN is the COMPLETE B complex ...

Most vitamin, B deficiencies are multiple ... and therefore require the complete B complex for thoroughly effective results.

Cereals, liver, and yeast are the richest, most important source of vitamin B complex. But not all the lesser known B factors are present in each of these 3 sources.

Elixir Bepadin, I.V.C., however, combines all 3 sources—rice bran extract, liver concen-

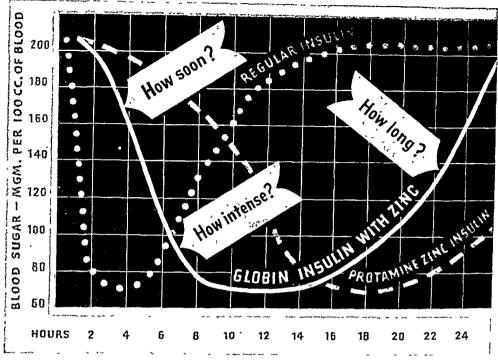

trate, yeast extract—to supply in Natural form the complete B complex.

Added... are thiamine hydrochloride, riboflavin, pyridoxine hydrochloride, and calcium pantothenate—in an appetizing and delicious sherry wine vehicle.

Available in 16-oz. bottles. A product of the International Vitamin Corporation, "The House of Vitamins," New York, Chicago, Los Angeles.

## A New Type of Insulin Action

A diagrammatic representation of the effects of comparable doses of various insulins on the blood sugar level of a fasting diabetic patient.

## 'WELLCOME' GLOBIN INSULIN WITH ZINC

'Wellcome' Globin Insulin (with Zinc), a new advance in diabetic control, offers a new type of insulin action.

- 1. How soon?—Rapid onset of action usually beginning within two hours after injection.
- How intense?—A strong prolonged daytime effect with maximum intensity during the patient's waking hours.
- 3. How long?—Diminishing action at night beginning at about the sixteenth hour after injection, thus minimizing the possibility of nocturnal insulin reactions.

'Wellcome' Globin Insulin (with Zinc) conforms to the physiologic needs of the patient.

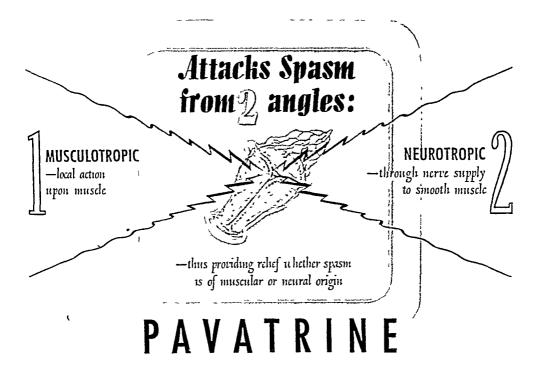

A single injection daily has been found to control satisfactorily most moderately severe and many severe cases of diabetes. It provides a rapid onset of action; strong prolonged effect during the day when most needed; and nocturnal waning of action. Insulin reactions at night are rarely encountered. 'Wellcome' Globin Insulin (with Zinc), a clear solution, is comparable to regular insulin in its freedom from allergenic skin reactions.

'Wellcome' Globin Insulin (with Zinc) was developed in the Wellcome Research Laboratories, Tuckahoe, New York. Registered U.S. Patent Office No. 2,161,198. Available in vials of 10 cc., 80 units in 1 cc.

### IRON DEFICIENCY ANEMIAS

For the rehabilitation and management of patients suffering from Iron Deficiency Anemias, The Arlington Chemical Company offers to the medical profession two effective hematinics.

### ARL-CU-FER\*

Clinical and biochemical studies supported by the Wi-consin Alumni Research Foundation and others have established that iron is best utilized in the presence of copper. ARL-CU-FER, presents inorganic iron and copper in the recommended proportions.

DOSAGE: Adults and children, one to four tablets a day, according to the severity of the Anemia.

SUPPLIED in bottle- containing 60 tablets.

## PRO-CU-FER\*

Another hematinic that retains the optimal iron-copper ratio, but offers the further advantage of iron combined with protein rendering it alkali-soluble. This promotes a more rapid absorption from the small intestine.

Euch PR	O-CU-FER 1	ablet .	represents	:
Iron			. 25 mgm	s
(Chen	nically combi	ned wi	th protein	)
Copper			1.25 mgm	s
	opper Sulfate		-	

DOSAGE: One to four tablets daily, for adults and children, according to requirements.

SUPPLIED in bottles containing 60 tablets.

Both ARL-CU-FER and PRO-CU-FER tablets are pleasant-tasting and non-staining. They may be chewed, swallowed whole, or allowed to dis-olve on the tongue. These preparations are manufactured under a license from Wiscon-in Alumni Research Foundation—Hart patent 1,877,237.

Our men call it the "green bullet." Shining green, it's as swift to solace as the deadly kind is to strike.

When a man's wounded, the "green bullet" is administered along with first aid. Gently it lets him slip off into sleep, cushioning his nerves against the shock of injury until he can be moved to the base hospital, where physical recovery can begin, unhindered by scars of the mind.

Making gelatine for the capsules that hold this green bullet and other pharmaceuticals is one of the war jobs being done by the makers of Knox. Another is the manufacture of gelatine for such special uses as X-raying metal castings...blue printing... map-making...aerial photography of camouflage.

The makers of Knox are able to meet these exacting specifications through rigidly controlled manufacturing processes and close laboratory supervision. These are the same methods that have made Knox Gelatine a standard of purity and quality for more than a half-century.

KNOX GELATINE Johnstown, New York

# Important Wartime change in Biolac!

# Borden's complete infant formula

To conserve vital tin, we are now packaging Biolac in 13-fl.-oz. cans instead of the former 16-fl.-oz. size. The new Biolac is more highly concentrated but the new smaller can contains identically the same food values.

Now each fl. oz. of Biolac should be diluted with  $1\frac{1}{2}$  fl. ozs. of water and not 1 fl. oz. as formerly.

Briefly, the situation on Biolac is this ...

When it became necessary to package Biolac in 13-fl.-oz. instead of 16-fl.-oz. tins, we set our chemists to work to concentrate the food elements to fit the container.

Tests of the new concentrate show identical food values in the smaller container. The new container still makes one full quart of standard formula.

Biolac still provides all nutritional

needs of the young infant except vitamin C. The price remains the same.

# Change in Formula-Making Directions

For standard formulas the new, more concentrated Biolac should be diluted with 1½ parts water (instead of using equal parts of Biolac and water).

For detailed information write to Borden's Prescription Products Division, 350 Madison Avenue, New York 17, N. Y.

NO LACK IN

BIOLAC

Borden's complete infant formula

Biolac is prepared from whole milk, skim milk, lactose, vitamin B<sub>1</sub>, concentrate of vitamins A and D from cod liver oil, and ferric citrate. Evaporated, homogenized, sterilized.

That is Ready Now...

Many objects that we live with promise to be improved—after the war. All of us will watch for these with great expectations. But the physician charged with the management of biliary deficiencies need not wait for one such that improves living. A lately bettered product of chemically pure substances for bile stimulation and replacement is at hand now. This is

# OOXYCHOL

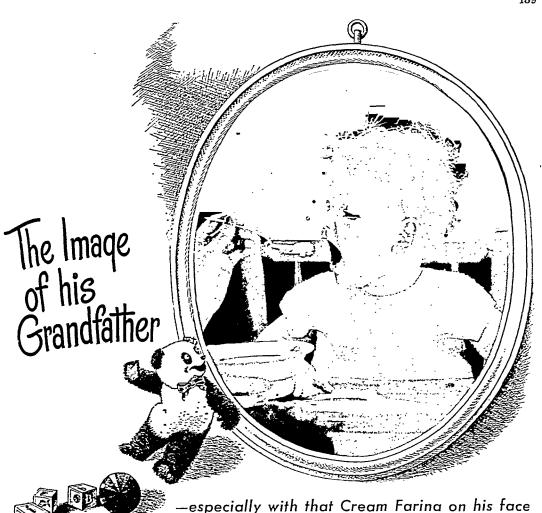

Composed of dehydrocholic and desoxycholic acids, Doxychol causes the washing of mucus and stagnated material from the ducts by markedly increasing the fluid bile. Of equal consequence it promotes the digestion of the fat portion of the diet and thereby gains energy for the patient.

These specific substances in one convenient preparation are available in Doxychol Tablets; in bottles of 100, 500, and 1000.

# George A. Breon & Company

New York Atlanta KANSAS CITY, MO. Los Angeles Seattle

T WAS just about 96 years ago that mothers first began wiping Heckers'
Cream Farina off the eager little mugs of American babies.

And it was a hit from the start—with the children, with the mothers, and with the horse-and-buggy doctors as well. It was recommended and approved by the pioneers in child welfare. It soon won recognition as a first solid food for babies.

Today's babies are even luckier, because the delicious, nourishing heart-of-the-wheat is scientifically enriched with Vitamin B<sub>1</sub>, niacin and nutritional iron. And this enrichment is

done with the same scrupulous care that marks every step in the making of this famous breakfast cereal.

# H-O OATS is the next step-up in children's diet

For body-building proteins, oats are richer than any other grain. Then, too, H-O Oats give children a

special pan-toasted flavor they can't resist. It's a High-Output breakfast, and its cost is so small it isn't even worth mentioning.

# HECKERS' Cream Enriched FARINA

A Product of THE BEST FOODS, INC.

Today, more than ever, the increased number of overworked physicians is entitled to every available facility in the continuing direction and care of chronic cases of circulatory, vascular and rheumatic disorders. Nature localized at Saratoga a rich en-

dowment of naturally carbonated mineral waters. Here are waters of established therapeutic value in treating conditions where external or internal use of them is indicated. And here New York State has organized and built around these natural agents facil-

ities for your use as a practicing physician. The Spa (whose medical staff does not practice) administers only the treatments prescribed by you. The local specialist you choose for your patient's stay at the Spa will give the desired supervision. The relaxation achieved at the Spa brings relief from pressures and tensions and thus prepares the patient for the full benefit of your con-

tinuing medical direction. We will gladly send you the professional publications of the Spa . . . physician's sample carton of the bottled waters with their analyses. Address W. S. McClellan, M. D., Medical Director, Saratoga Spa, 155 Saratoga Springs, N.Y.

In the increasing incidence of B-complex deficiency — increasing because of greater energy demands and lessened food availability — Noviplex deserves the physician's consideration. It provides the essential components of the B-complex in approximately the proportions required by the human organism. Since it is largely derived from high potency yeast concentrate, Noviplex provides all the naturally occurring factors, including choline, inositol, and biotin.

# A million pints of blood

WITH the first rumblings of global war, foresighted Army, Navy, and Red Cross planners brought into being an organization to provide plasma for the armed services. For months hundreds of thousands of patriotic Americans have appeared at bleeding stations to give a portion of their blood so that a wounded fighting man might have a better chance to live.

Invited at the outset to participate in this magnificent project, Eli Lilly and Company rapidly prepared for the intricate job of making stable, dried plasma from whole blood. Today more than a million bleedings have been processed without one cent of profit to the company.

# Evolution

American medicine is to a certain extent today following a course parallel to that of American labor or, in fact, labor in any country which, originally agricultural, has undergone industrialization. It might be well for those concerned with the formulation of the future policies of medicine and its institutions to consider this parallel.

Not so long ago the journeyman laborer was a hand-tool worker, independent, owning his own tools, working what hours he pleased, and under circumstances of great freedom and latitude of movement. But with the advent of power machinery, the picture rapidly altered. True, the hand-tool worker still continued to exist, but his numbers became smaller in comparison with machine operators. These latter did not own the machines they operated or the factories in which they worked. Wages, hours, and working conditions were none of the best for many years.

None can fail to see the similar evolution of medicine in the same period of time. The rise of the hospitals and the medical centers, made possible largely by the profits of intensive industrialization of the nation and the research aided by large "foundations" whose capital resources were derived from the same source, has to a certain extent accomplished the partial industrialization of a large part of the medical profession, in that it works in hospitals it does not own or control, and with tools, a growing number of which may be likened to the machine tools of industry: the cyclotron and the electron

microscope, for example. This decade is witnessing the enormous expansion of the medical services of an increasing number of large industrial establishments as well as of smaller plants. The number of physicians working whole time in these services is on the increase. The tendency to concentrate more and more of medical practice about the hospitals is well established. It is not a matter for wonder than an intensified and expanded industrialization of the nation should thus create a partially industrialized medical profession.

There arise in consequence many problems, economic and social, which medicine is sometimes reluctant, at other times ill equipped to face. What shall be the status of the physician-employee? Is he a laborer for hire? Or a professional man for rent? Where does he belong in the labor-management setup? In hospitals, most physicianemployees are not members of the medical staffs. Where do they stand in industrial medical services? Are they independent contractors?

Certainly such physician-employees in industrial establishments serve both management and labor and can be wholly independent of neither one, but must not, on the other hand, become a dependent of either. Can such a middle status endure, considering the quasi-judicial function implied in the maintenance of such a nice balance?

How shall conditions of employment be safeguarded? What is the effective collective bargaining power of medical societies, either local, state, or national, with respect to physician-employee contracts with industrial or hospital employers?

These and many more are some of the problems and questions arising out of the increasing industrialization of medical practice which were unknown to the journeyman hand-tool workers of the middle eighties or the private practitioner of medicine of the recent past. Even now, with many of these complicated relationships of medicine with industry and the hospitals still unsolved, new relationships with government are being created. E.M.I.C. is just getting into operation, with the several state departments of health attempting to interpret and to administer in their jurisdictions the federal regulations governing this type of medical service, in consultation with the state medical societies. Here is federal law and federal money covering maternity and infant care for certain classes of soldiers' dependents, operating through state agencies and creating between the private practitioner, the hospital, and the state department of health a new relationship of somewhat extraordinary complexity. A novel feature of this type of medical service is the arbitrarily fixed fee for services set by the Children's Bureau,

which is binding upon both the donor and the recipient of the services by regulations of the Bureau which have the force and effect of law.

It is apparent from the trend of proposed legislation, as well as from a study of existing laws and regulations, that in the opinion of many persons even the present industrialization of medical practice does not go far They would have it completely federalized. This tendency is in line with the undoubted trend toward the breakdown of local and state autonomy in favor of federal control. There is nothing novel about it, except that it has been relatively untried in this country. War, however, tends to hasten the ordinarily slow processes of evolution. Medicine itself, acting in an advisory capacity to the American people, can only present to them its wealth of experience with the philosophy and practice of the art and science which it has developed.

What the people will have to say concerning the federalization of the profession or of the nation's economy seems yet to be anybody's guess. What the people want they can have by the orderly processes of law and elections guaranteed by the Constitution.

# Workmen's Compensation

In a release to the newspapers on December 20, 1943, Dr. Thomas A. McGoldrick, President of the Medical Society of the State of New York, had this to say:

"In view of the allegations of fee-splitting and 'kickbacks' to doctors in Workmen's Compensation work made in the course of the Moreland investigation, I wish to present a few facts to the public.

"First, I wish to state that the Medical Society of the State of New York strongly disapproves and always has disapproved of fee-splitting and so-called 'kickbacks' to doctors engaged in Workmen's Compensation work or in any other form of medical care. Such practices are contrary to the ethics of the profession.

"The Medical Society of the State of New York has been accused of taking no action on the allegations made against certain doctors.

Such is not the case. A decision of the Attorney General, delivered early this year, revealed that state and county medical societies had the power to summon offenders, put them under oath, and obtain testimony. Prior to this time the Society was advised that it did not possess this power. As a result of the more recent decision, the medical societies concerned have been conducting hearings in the case of accused physicians in accordance with the provisions of the Compensation Law and the code of ethics of the American Medical Association and the Medical Society of the State of New York. Already approximately 500 cases have been tried by the medical societies. Every remaining case will be investigated and any person found guilty will be justly punished.

"No group or individual is more interested in preventing and eliminating unethical and unfair activities in the practice of medicine than the State Medical Society and its constituent county medical societies. The public may rest assured that every effort will be exerted to eradicate dishonest and reprehensible medical practices. The majority of the medical profession is in accord with the high ethical principles to which it is committed.

"At the proper time the Medical Society of the State of New York will make recommendations for amendments to the Workmen's Compensation and Education laws, which it hopes will facilitate the detection of offenders and prompt disciplinary action."

This statement should leave in nobody's mind any doubt that continuing action by the state and county societies will proceed as the evidence warrants. "In 1937," says Dr. David J. Kaliski, Director of the Bureau of Workmen's Compensation of the Medical Society of the State of New York, "the then Industrial Commissioner, Elmer F. Andrews, in answer to a letter . . . . stating that in the opinion of our Council and of his Department we did not possess the power to subpoena witnesses, acknowledged this fact and agreed to my suggestion that such investigations and hearings requiring the oath and subpoena be held by the Industrial Council of the Department of Labor.

"Since then," states Dr. Kaliski, "this matter has been discussed (by the Society) and it was always our belief that all we could do was to bring in a doctor and interrogate him, but could go no further. Section 13-d of the Workmen's Compensation Law does not contain a provision giving the Medical Society's Compensation Boards the right to issue subpoenas. . . . This (power) is included in the Education Law under Section 1265, where the Grievance Committee is given the power specifically. . . . "

On April 26, 1943, the Director of the Society's Bureau of Workmen's Compensation wrote to Acting Industrial Commissioner Michael J. Murphy as follows, in part: "At a recent meeting of the Industrial Council to which you invited me and in conversations with you during the past few weeks, I have advised you of the willingness and desire of the medical societies to fulfill their responsibilities under the Workmen's

Compensation Law to hold trials where either the investigational hearings conducted by Mr. Godfrey P. Schmidt of your Department or the testimony before the Moreland Act Commissioners indicates that physicians may be guilty of violations of Section 13-d of the Workmen's Compensation Law. I was pleased to concur in your suggestion that Mr. Schmidt conduct investigational hearings preliminary to either exoneration or trial of the physician involved. . . . I have been present during the hearings conducted by Mr. Schmidt and it is my opinion that they have been thorough and eminently fair and should be continued. . . . .

"I would respectfully call your attention to the rules and regulations laid down by the Industrial Council governing trials by medical societies. These regulations require that specific charges be served and a period of at least twenty days be given to the accused before he is required to appear before the Board for trial. In this connection, as I have on previous occasions, I again request you to obtain an opinion from the Attorney General as to the power of the Compensation Boards of the Medical Society to administer oaths and to subpoena necessary witnesses.....

"It is of course apparent that unless the Society is clothed with the necessary power of subpoena and the administration of the oath, it cannot successfully carry out these functions, let alone seek out certain violations of the Law. I believe these questions as to our authorization under the Act should again be submitted to the Attorney General for an opinion...."

On May 19, 1943, the Acting Industrial Commissioner transmitted to the Director of the Society's Workmen's Compensation Bureau the opinion of Mr. Nathaniel Goldstein, Attorney General of the State of New York, as follows in part: "My reason in concluding that a medical society, committee, or board has the authority to administer an oath is founded upon the same reason stated in connection with their power to issue subpoenas pursuant to Section 406 of the Civil Practice Act, that they are authorized by Section 13-d of the Workmen's Compensation Law 'to take or hear testimony. . . . in relation to a matter concerning which he or it has a duty to perform.....

"I therefore conclude that medical societies involved in the prescribed investigation and hearings have the direct and personal power to secure the attendance of witnesses by the issuance of subpoenas; and, likewise, have the power to administer oaths to such witnesses as may appear and testify before them."

It is thus apparent that not until the early part of this year could the Society, now apparently vested with power under this opinion, proceed fully to carry out its obligations. "Every remaining case," as Dr. McGoldrick has said, "will be investigated and any person found guilty will be justly punished."

# Mene, Mene, Tekel, Upharsin

These were the words written upon the wall at Belshazzar's¹ feast. What is their significance for American medicine today? Translated freely, the words mean: the years of your sovereignty are numbered and finished; you have been weighed in the balance and found wanting; your kingdom is divided and given away. In the role of very modern Daniels, Messrs. Wagner, Murray, and Dingell have done a job of translating the handwriting into proposed federal legislation! Perhaps in the hope that a chain of gold will be put about their necks?² It is a delicate hope.

At the hour of this writing "the fingers of a man's hand" have come forth and are writing "over against the plaister of the wall" the fact of the seizure of the struck coal mines by the government. In Congress there lies embodied in S. 1161 and its companion bill the mechanism for the virtual seizure of the medical profession by the government, compensated by the sum of \$3,048,000,000 annually of the taxpayers' money, but containing no provision for the return of the profession to its present status of free enterprise after the war or at any other time.

Perhaps it can happen here. It can happen if the people neglect to say they do not want it. Or if they are indifferent to whatever happens. Something like it has happened in Germany, in England, in New Zealand. In the United States the medical and hospitalization provisions of S. 1161 are tied in with many other aspects of social security of which organized medicine approves. But doctors cannot be expected to applaud nor will the public approve if rightly informed of a bald-faced attempt to sell the entire

medical profession into slavery to the Surgeon General of the U. S. P. H. S. forever. If this bill becomes law, it will be possible to say of this official: "Whom he would he slew; and whom he would he kept alive; and whom he would he set up; and whom he would he put down."

Seizure by government of struck mines to maintain absolutely essential coal production in wartime is one thing. Attempted seizure of the medical profession and its affiliated institutions, in none of which is anyone on strike but, on the contrary, producing to capacity with 45,000 and more of its limited physician personnel in the armed services, is quite another. The significance of the handwriting on the wall is the attempt of the government to expropriate and socialize the medical profession of the United States, to sell it into virtual slavery to the Surgeon General of the U.S. P. H.S. when the large number of physicians who are serving the nation in the armed services are in no position to do anything about it. The fact that the A. F. of L. and the C. I. O. seem to be in favor of such seizure of the profession of medicine and have assisted in the writing of the medical and hospitalization provisions of the bill to accomplish it does not, in our opinion, particularly recommend it in the light of the records of the performance of these gentlemen with respect to the public interest. But politics makes strange bedfellows, and it may come to pass that Daniels Wagner, Murray, and Dingell may not, after all, have been such accurate interpreters, politically speaking, of what the fingers of a man's hand were indeed writing over against the plaister of the wall.

# THE DEGREE, THE EXTENT, AND THE MECHANISM OF MUSCLE SPASM IN INFANTILE PARALYSIS

HARRY D. BOUMAN, M.D.,\* and R. Plato Schwartz, M.D., Rochester, New York

NURING the past three years the medical profession has been invited to change its concepts on the mechanism and treatment of infantile paralysis. Our attention has been drawn to the treatment of muscle spasm, and those who advocate this change speak of the "ever present and damaging effect of spasm"1 on muscle function.

The treatment thus advocated, and now known to the general public as the Kenny treatment of infantile paralysis, makes apparent the need for an investigation of muscle spasm with the help of well-established and accurate scientific methods of recording muscle function.

Those who initiated the Kenny concept and method of treating patients during the acute stage of infantile paralysis have offered clinical observations to substantiate their claims. limitation of the new concept to opinions based on clinical observations was further narrowed by the exclusion of methods for determining the initial distribution and degree of muscle weakness or paralysis before starting treatment. Moreover, no clear pathologic basis for the asserted importance of muscle spasm in the development of muscle weakness has as yet been presented by the proponents of the Kenny con-

In general the established (orthodox) point of view was in full agreement with the teachings of Lovett,2 who had clearly defined the clinical course of the disease in terms of three stages of pathology:

- 1. The Stage of Onset.—Pathologically it is an acute hemorrhagic myelitis and meningitis, and clinically the child is suffering from that, combined with an infection more or less severe. It covers the period from the beginning of the illness until the disappearance of the tenderness because tenderness must be accepted as evidence of an active process still existent in the cord. In those exceptional cases where tenderness is absent, it may be assumed that this stage lasts
- 2. The Stage of Convalescence.—Pathologically, the products of the hemorrhage are being

from four to six weeks.

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 6, 1943.

Aided by a grant from the National Foundation for Inlantile Paralysis, Inc.

From the Department of Surgery, Division of Orthopsedies, University of Rochester, School of Medicine and Dentistry, Rochester, New York.

\* By invitation

absorbed, edema and perivascular infiltration are diminishing, and, physiologically, the motor area of the brain is trying to send impulses to the affected muscles, only to find certain paths partly or wholly blocked. Clinically, the child is more active and is trying to use the affected parts: tenderness has gone, but the power to execute certain movements may be impaired or lost. Notwithstanding this, there is a continuous gain, under all conditions of treatment or neglect. So-called "trophic" disturbances begin to appear now or later—circulation is impaired, affected members are atrophied and do not grow as they should, and deformities begin to develop. This stage begins with the disappearance of tenderness and lasts for about two years.

3. The Chronic Stage.—Pathologically, edema and perivascular infiltration have long since disappeared, the meningitis has healed, and in place of the destroyed areas in the cord are found focal glioses. Clinically, the case is apparently stationary or retrograding. Spontaneous improvement is much less noticeable than it was in the previous stage, and in most cases it seems to have stopped and so-called trophic changes are present. Deformities from muscular contractions and gravity have occurred in many cases, and further improvement without treatment is not to be hoped for. This stage apparently begins about two years from the onset and continues through life.

This simple and rational statement of the clinical course of the disease was a natural companion to a therapeutic program based on the known character and extent of the pathology of infantile paralysis. By this time there was sufficient understanding of cause and effect that the Hunter-Hilton-Thomas principles of "physiological rest" were applied in the treatment of the acute stage of this disease. For the later stages, there was an equally well-defined procedure of muscle training also based on the prevailing knowledge of pathology which provoked muscle weakness or paralysis.

The invitation to embrace the presence of "spasm as a cause of muscle weakness and paralysis" was a request that we should deny the validity of all that had been learned in the past one hundred and fifty years regarding this disease that annually strikes terror in many communities.

The proponents of the role of muscle spasm have not offered scientific evidence to disprove

the pathology as established since the days of Meden (1887); neither have they followed established procedures which require more than clinical observation to support their claims.

Therefore, before accepting the invitation to embrace this concept and reject all that had gone before, it was necessary to determine the manner in which spasm manifested itself during the acute stage of infantile paralysis.

As stated in a previous publication, we found that "spasticity was present in infantile paralysis. Whether the spasticity is actually responsible for weakening of the muscle or whether it is a phenomenon which is merely another consequence of the disease is a question which cannot be answered at the present time."

Muscle spasm, as it is clinically known in cases of spastic paralysis and similar disease, is most easily recognized by the resistance of the affected muscles to a passive stretch. While a normal muscle on passive stretching gives rise to only a short contraction, the spastic muscle produces a much more prolonged contraction which often results in muscle clonus. It is certainly true that a muscle clonus is rarely, if ever, found in infantile paralysis. It is also clear that the clinical observance of a resistance to stretch which is greater than that of a normal muscle will in most cases be difficult. Not only will it be hard to estimate quantitatively the degree of such resistance; it is also quite possible that such spasm may be too weak to be noticed in a careful clinical examination. It is well known that a muscle can contract without any visible movement. It is reasonable, then, to assume that a reflex contraction on stretching a muscle might be too weak to be observed clinically.

It is, however, possible to record the minimal contractions of a muscle, which are too weak to be either seen or felt, by one of two methods.

When a muscle contracts, it produces both sound and electricity. Bouman and Van Rynberk' have studied the muscle sounds of human muscles during voluntary contractions. The technic of these measurements, however, offers certain difficulties which make it less easily applicable to clinical investigation.

The electricity produced by a muscle during contraction, the so-called action current, can more readily be applied in clinical investigation. Electrodes can be applied to the skin over the muscle that is to be investigated, and the action currents obtained can be amplified and recorded. Stetson and Bouman<sup>5</sup> have shown that it is possible to obtain action current records from fairly closely adjacent muscles by recording through the skin, with hardly any interference between the recorded muscles. Improvements

in the technic now make it possible to record muscle action currents without shielding the patient. The maximal useful sensitivity of the amplifiers is I mm. per microvolt; the sensitivity most commonly used is about 1 mm. per 5 microvolts.

We now use four action current amplifiers and a multiple recording oscillograph to provide for the simultaneous recording of action currents from four different muscles, together with an indicator signal of the beginning and the end of the passive movement. Precise calibration of the amplifiers gives assurance of their absolute sensitivity and also defines the equal sensitivity of the four amplifiers. Development of a special attenuator system has reduced this calibration to a routine procedure which can be carried out in a few moments before the beginning of the actual recording.

Extent of Muscle Spasm.—In Miss Kenny's original concept spasticity was supposed to be a property of the antagonist of the wakened muscle. Our action current records confirm this statement.<sup>3</sup> Passive stretching of the antagonist of the weakened muscle shows a burst of action currents characteristic of a spastic muscle.

Muscle spasm, however, is also found in those muscles whose antagonists do not show evidence of weakening. In patients, for instance, in whom muscle weakening during the entire course of the disease was limited to the legs, spasticity was found to be present in the arm muscles. The neck muscles also show spasticity in nearly all patients.

In the third place, spasticity is found in the weakened muscle itself and is in many instances of considerable magnitude. Moreover, it is found that in many cases the spasticity in the weakened muscles is actually stronger than the maximal voluntary contraction which the patient is able to perform. This evidence indicates that spasticity is a general phenomenon in the early stages of infantile paralysis.

Degree of Spasticity.—The degree of spasticity varies considerably in different patients, and in different stages of the disease. There seems to be no clear relation between the degree of spasticity and the seriousness of the weakening of the muscle. A discussion of the change in degree of spasticity during the course of the disease is outside the scope of this paper. We shall discuss later the relation between the spasticity of the muscle and the strength of its voluntary contraction.

In complete paralysis there is no spasticity. It should be stressed, however, that we consider complete paralysis to be present when there is no evidence of action currents from stimulation by voluntary effort or stretch reflex. Absence of

observable movement is not a valid indication of the absence of activity in the muscle fiber. It is possible for even a normal individual to perform a contraction which is too weak to give a visible movement; action currents, however, show the presence of activity in at least a certain number of muscle fibers.

In most instances spasticity of a muscle is most easily recorded by stretching the muscle. In a considerable number of instances, however. spasticity is evident without passive movements. A similar phenomenon occurs in spastic paralysis. Hoeffer has shown that in such a muscle it is usually possible to find a certain position in which the action currents have a minimum which approaches zero. The same thing occurs in infantile paralysis, being especially clear cut in the neck and shoulder muscles. When the head is supported in a certain position, action currents are almost absent. A position only slightly different from the minimal position will, however, bring the action currents out again in full force.

This position for minimal action currents, however, is not constant in the same patient. It varies from day to day. Also it is not the same for symmetric muscles. That there is a position in which all muscles of an extremity could be permanently immobilized, with the assurance that all action current evidence of spasticity would be constantly absent, is, therefore, subject to question.

Mechanism of the Spasticity.—Even though it may be too early to offer a complete picture of the changes in the neuromuscular mechanism which are the basis of the phenomena observed in the early stages of infantile paralysis, some facts seem to give us at least a working hypothesis. In the first place, evidence at hand indicates that spasticity is a reflex phenomenon and is not due to a process localized in the muscle itself, such as muscle fibrillation or muscle inflammation. It is well known that a muscle deprived of its nerve supply may show fibrillation; however, in our cases in which no voluntary or reflex contraction of the muscle could be obtained, spasticity was also absent.

That spasticity is of reflex origin can be seen from our simultaneous recording of four muscles. If we record, for instance, from two gastocnemii and the two anterior tibial muscles in the same patient, we find that passive stretching of one of the four muscles will result in spasticity in all four muscles—i.e., spasticity spreads to both the ipsilateral antagonist and to both the homilateral muscles, which can be explained only if spasticity is a reflex phenomenon.

Spasticity spreads to the antagonist and other muscles not only in passive stretching of the

muscle but also on voluntary contraction of the muscle. It is clear that this phenomenon is different from what is commonly observed in spastic paralysis in patients or in animal experiments by transection of the spinal cord. According to Sherrington's principle of reciprocal innervation, contraction of a muscle should result in relaxation of the antagonist, and not, as in the case of infantile paralysis, in contraction (spastic-This reversal of reciprocal innervation is important in the maintenance of spasticity in infantile paralysis. A minor contraction of one muscle would set off spasticity in the antagonist, and this spasticity, being in itself nothing but a prolonged form of contraction, will in turn provoke spasticity in the original muscle, and so on. We are dealing, then, with a vicious circle in which one muscle keeps its antagonist going and the antagonist, in turn, maintains the spasticity in the original muscle. Only when the spasticity has disappeared during the course of the disease, or when one of the two muscles is completely paralyzed so that it can no longer produce spasticity, will this vicious circle be broken.

This reversal of the reciprocal innervation raises a question as to what constitutes the difference between the mechanism underlying the spasticity in spastic paralysis due, for instance, to a transverse lesion of the spinal cord, and the spasticity that is found in infantile paralysis. It is generally assumed that the spasticity which results from a transverse lesion of the spinal cord is due to a lack of inhibitory impulses coming down to the motor neurons from the higher centers via the pyramidal tracts. In this case the influence of the brain centers has been eliminated, resulting in the phenomena that are known in spastic paralysis due to transverse lesions.

Evidently the mechanism in infantile paralysis is different, and it might be supposed that this is due to the fact that in infantile paralysis the lesion is much closer to the motor neurons of the muscles involved than in the case of the transverse lesion. In other words, could it be possible that the parts of the spinal cord between the motor neuron of the muscles examined and the lesion are responsible for the difference in phenomena between transverse lesion spasticity and infantile paralysis spasticity? Van Rynberk and his coworkers, have experimented with dogs with one isolated spinal cord segment. Three segments above and three segments below the isolated segment were destroyed in such a way that the isolated segment survives without any neural connections to other spinal cord segments. The skin area innervated by this segment could be stimulated and the skin reflexes obtained from the usual type of spinal cord animal. The muscle reflexes from the muscles innervated by this area, however, are completely changed in character. If one of these muscles is stimulated, either by deep pressure through the skin or by stimulation of the muscle after removal of the skin, a reflex contraction occurs in all muscles innervated by the segment. Instead of the usual type of muscle reflex of the spinal animal, which includes reciprocal inhibition, they obtain in the single segment animal a generalized contraction of all muscles of the same spinal level as seen when one of the muscles is stimulated.

It is clear that these phenomena are similar to those that we described in patients who were affected by infantile paralysis. It follows then that the patient who is affected by infantile paralysis is, so far as his reflex mechanism goes, comparable to the animal with a single isolated segment, and not to the usual type of spinal animal. This must mean, then, that in infantile paralysis the lesion should be located close to the motor neurons themselves. That higher parts of the spinal cord have an inhibitory effect on the lower parts of the spinal cord has become clear from the recent work of Lloyd (see below).

He investigated the inhibitory effect on a motor neuron reflex of impulses delivered to a sensory root close to the level of the root which is being examined and also of stimulates of sensory nerves further away from the level of the reflex being examined.

Our considerations then lead us to the conclusion that in infantile paralysis the inhibitory impulses from the higher centers are blocked in very close proximity to the motor neurons. This might take place either at the synapses of these fibers at the motor neurons or it might be due to the failure to conduct in internuncial cells inserted in the fibers coming from the higher centers and located in close proximity to the motor neurons. It should be noted that the voluntary contractions in the affected muscles are also decreased. Evidently the motor impulses are not able to reach all motor neuron cells unimpeded. If the motor tracts and inhibitory tracts are separate up to the anterior horn cells, the conclusion would have to be drawn that the transmission difficulty occurs in the synapses on the motor horn cells. This would be in agreement with the generally accepted anatomic picture which places the lesion of infantile paralysis in the motor horn cells. However, even if the motor horn cells are no longer able to receive inhibitory impulses from higher centers of the cord, or the motor impulses which give the voluntary contraction, they are

still able to receive the impulses coming from the muscles of about the same spinal levels. We found in many records of seriously weakened muscles that the reflex spasticity is actually stronger than the maximal voluntary contraction. This must mean that some of the motor neurons are no longer able to receive impulses from higher centers, either inhibitory or excitatory, while they are still able to receive impulses from the short reflex arcs. We can go even farther than this. We mentioned above that spasticity is found even in those muscles which showed no weakening of their voluntary contractions. In this case only the inhibitory impulses from other parts of the spinal cord have disappeared, while both the voluntary motor impulses and the excitatory impulses from the short reflex arcs are able to reach the motor neuron cells.

Recent investigations have produced considerable insight into the spinal mechanism of the muscle reflexes. Renshaw<sup>9</sup> stimulated dorsal roots of the spinal cord and ledoff action currents from the ventral roots. He determined the time interval between the stimulus and the first group of impulses in the ventral root record. Taking into account the conduction time in the spinal cord, he found that there was an extra time needed for transmission of about 0.65 msec. This time is known to be of the order of magnitude of a single synaptic delay. In other words, there are impulses which traverse the spinal cord from sensory to motor side and meet only one synapse, which must then be located at the motor neuron. There are later groups of action currents in the ventral roots which are due to those impulses which have passed through more than one synapse in the spinal cord. Lloyd10 has extended these experiments. Instead of stimulating the dorsal roots, he stimulated the sciatic nerve and its branches, again taking into account the conduction time of the impulses from the locus of stimulation to the spinal cord. He found that if the sensory fibers in a muscle branch of the sciatic nerve are stimulated, the time interval allows for only one synapse in the spinal cord. If a cutaneous branch is stimulated more than one intraspinal synapse is involved. This means that the proprioceptive impulses meet only one synapse in the spinal cord, which must then be located at the lower motor neuron. In other words, the proprioceptive reflex are of a muscle does not involve internuncial neurons in the spinal cord but its sensory fiber reaches directly to the motor neuron. This so-called two-neuron arc reflex can now be inhibited by impulses from other dorsal roots. Lloyd11 shows that inhibitory impulses from adjacent dorsal roots again have their effect at the lower motor neurons, the time relations between the

1

. E. (1)

中国在日本日本日本日本日本日本日本日本日本日本日本日本

inhibitory stimulus and the beginning of the inhibition do not allow for more than one synapse. Again on stimulation of the brachial plexus, Lloyd<sup>12</sup> finds an inhibitory effect which is due to a direct action in the motor neurons, while pyramidal excitatory impulses reach the motor neurons via internuncial neurons.13 It appears then that the inhibitory functions of adjacent segments of the spinal cord are due to an immediate effect on the motor neurons. infantile paralysis these inhibitory impulses seem to have disappeared, and the result is a phenomenon similar to that in the single segment animal. Our conclusions seem to agree with the classical localization of the lesion in and related to the motor neurons. In fact, this means that the motor neurons can no longer be excited by the direct inhibitory impulses which reach them through short reflex arcs, while the excitatory impulses still stimulate the anterior horn cells.

Thus we see that in infantile paralysis in the weakened muscles the motor neurons are no longer influenced by either the impulses needed for a voluntary movement or the inhibitory impulses, while they are still being influenced by the excitatory impulses reaching them through the short reflex arcs. At the motor neurons arrive three separate groups of impulses: (1) the impulses giving the voluntary contractions, (2) inhibitory impulses, and (3) excitatory impulses from the short reflex arcs. We saw above that in the weakened muscle only the third group is able to influence certain motor neurons. However, we mentioned that in infantile paralysis even the muscles which show no evidence of weakening can be spastic. It is clear on the basis of the explanation offered here that in that case only the inhibitory impulses fail to effect the motor neuron, while both the short reflex arcs and the voluntary impulses are still effective. In this "ay, spasm of the particular type encountered in infantile paralysis can be explained, owing to a decrease in the excitability of the motor neurons. Only when they lose their excitability completely does all evidence of voluntary motor function disappear, and with it disappears the last remainder of spasticity.

It appears then that the motor neuron can receive three separate groups of impulses. The recorded evidence indicates that in infantile paralysis the motor neuron may lose its exvitability to either one, two, or all three of these impulses. If only the excitability to inhibitory impulses is gone, the motor unit innervated by the particular neuron will show spasticity but no decrease in voluntary function. If both the inhibitory and voluntary impulses are no longer able to excite the motor neuron, spasticity will

be present while the muscle will show decreased function, and finally when all motor neurons have lost the excitability to all three types of impulses both voluntary contraction and spasticity of muscle will disappear.

# Summary

Spasticity is a general phenomenon in the early stages of infantile paralysis. It is independent of muscle weakening and appears in agonist and antagonist muscles which do not show weakening during the course of the disease.

This latter fact means that spasticity in a certain muscle is not automatically followed by weakening of its antagonist. In fact, spasticity and weakening are two separate phenomena, each dependent on disturbance of specific functions of the anterior horn cells. Recent findings in the physiology of the spinal cord have made it possible to offer a scientific explanation of the mechanism of muscle spasm in infantile paralysis.

The data obtained from the treatment of 22 infantile paralysis patients in regard to the course of improvement in muscle function and the disappearance of spasticity under treatment are now being summarized for early publication.

Discussion

Dr. R. Plato Schwartz, Rochester, New York-Infantile paralysis has been a serious problem since the severe Brooklyn epidemic of 1916. Since that time, this disease has provoked public fear and professional concern throughout the North and South American continents. For these reasons we are particularly grateful for the two papers which have

just been presented. The "New Developments in Infantile Paralysis" expresses the point of view of Dr. Don W. Guda-

kunst,\* Medical Director of the Foundation. We are grateful for this summary because it provides the basis for a frank discussion of some important questions which have developed in and which

<sup>\*</sup> New York State J. Med. 43: 1514 (Aug. 15) 1943.

obtained from the usual type of spinal cord animal. The muscle reflexes from the muscles innervated by this area, however, are completely changed in character. If one of these muscles is stimulated, either by deep pressure through the skin or by stimulation of the muscle after removal of the skin, a reflex contraction occurs in all muscles innervated by the segment. Instead of the usual type of muscle reflex of the spinal animal, which includes reciprocal inhibition, they obtain in the single segment animal a generalized contraction of all muscles of the same spinal level as seen when one of the muscles is stimulated.

It is clear that these phenomena are similar to those that we described in patients who were affected by infantile paralysis. It follows then that the patient who is affected by infantile paralysis is, so far as his reflex mechanism goes, comparable to the animal with a single isolated segment, and not to the usual type of spinal animal. This must mean, then, that in infantile paralysis the lesion should be located close to the motor neurons themselves. That higher parts of the spinal cord have an inhibitory effect on the lower parts of the spinal cord has become clear from the recent work of Lloyd (see below).

He investigated the inhibitory effect on a motor neuron reflex of impulses delivered to a sensory root close to the level of the root which is being examined and also of stimulates of sensory nerves further away from the level of the reflex being examined.

Our considerations then lead us to the conclusion that in infantile paralysis the inhibitory impulses from the higher centers are blocked in very close proximity to the motor neurons. This might take place either at the synapses of these fibers at the motor neurons or it might be due to the failure to conduct in internuncial cells inserted in the fibers coming from the higher centers and located in close proximity to the motor neurons. It should be noted that the voluntary contractions in the affected muscles are also decreased. Evidently the motor impulses are not able to reach all motor neuron cells unimpeded. If the motor tracts and inhibitory tracts are separate up to the anterior horn cells, the conclusion would have to be drawn that the transmission difficulty occurs in the synapses on the motor horn cells. This would be in agreement with the generally accepted anatomic picture which places the lesion of infantile paralysis in the motor horn cells. However, even if the motor horn cells are no longer able to receive inhibitory impulses from higher centers of the cord, or the motor impulses which give the voluntary contraction, they are

still able to receive the impulses coming from the muscles of about the same spinal levels. We found in many records of seriously weakened muscles that the reflex spasticity is actually stronger than the maximal voluntary contraction. This must mean that some of the motor neurons are no longer able to receive impulses from higher centers, either inhibitory or excitatory, while they are still able to receive impulses from the short reflex arcs. We can go even farther than this. We mentioned above that spasticity is found even in those muscles which showed no weakening of their voluntary contractions. In this case only the inhibitory impulses from other parts of the spinal cord have disappeared, while both the voluntary motor impulses and the evcitatory impulses from the short reflex arcs are able to reach the motor neuron cells.

Recent investigations have produced considerable insight into the spinal mechanism of the muscle reflexes. Renshaw9 stimulated dorsal roots of the spinal cord and ledoff action currents from the ventral roots. He determined the time interval between the stimulus and the first group of impulses in the ventral root record. Taking into account the conduction time in the spinal cord, he found that there was an extra time needed for transmission of about 0.65 msec. This time is known to be of the order of magnitude of a single synaptic delay. In other words, there are impulses which traverse the spinal cord from sensory to motor side and meet only one synapse, which must then be located at the motor neuron. There are later groups of action currents in the ventral roots which are due to those impulses which have passed through more than one synapse in the spinal cord. Lloyd10 has extended these experiments. Instead of stimulating the dorsal roots, he stimulated the sciatic nerve and its branches, again taking into account the conduction time of the impulses from the locus of stimulation to the spinal cord He found that if the sensory fibers in a muscle branch of the sciatic nerve are stimulated, the time interval allows for only one synapse in the spinal cord. If a cutaneous branch is stimulated more than one intraspinal synapse is involved. This means that the proprioceptive impulses meet only one synapse in the spinal cord, which must then be located at the lower motor neuron. In other words, the proprioceptive reflex are of a muscle does not involve internuncial neurons in the spinal cord but its sensory fiber reaches directly to the motor neuron. This so-called two-neuron arc reflex can now be inhibited by impulses from other dorsal roots. Lloyd11 shows that inhibitory impulses from adjacent dorsal roots again have their effect at the lower motor neurons, the time relations between the

give practical expression to her concept of spasm, the National Foundation allocated funds to create the instruments necessary for investigation of neuromuscular behavior as related to this theory of spasm.

At this point I wish to ask Dr. Bouman a question. Given a muscle which is completely paralyzed, have you recorded evidence of returning function? If so, what is the role of spasm in association with the return of function?

Furthermore, Dr. Bouman has stated his reasons for not recording muscle sounds in such a clinical investigation. I should like for him to tell us what other method, or methods, might be of practical value in conjunction with the action current amplifiers now in use?

In conclusion, I wish to state a personal conviction. The evidence at hand, of which Dr. Bouman's paper is a part, clearly indicates that spasm of skeletal muscles is a generalized phenomenon during the acute stage of infantile paralysis. Furthermore, the various ways in which it manifests itself are not detectable by clinical methods of examination, but, when revealed in action current records, can be explained on the basis of the established behavior of the neuromuscular mechanism as determined by reliable investigators. Finally, it is quite clear that because of Miss Kenny's concept of spasm, we now know from laboratory investigations that the function of the motor neurons may be impaired in one of three ways instead of in only one, as was believed in the past.

Dr. Bouman—The return of function in a completely paralyzed muscle which shows no evidence of action currents is quite possible. This happens in steps. There is first an increase in action currents during voluntary contraction combined with an increase in spasticity. Gradually this spasticity is reduced while the voluntary contraction strength remains. With the next increase in contraction strength there is again a temporary increase in spasticity and so on.

Another way to study the changes in the neuromuscular apparatus during the course of infantile paralysis would be to measure the excitability for instance, by means of measuring chronaxia. Chronaxia determinations have been tried and abandoned in many clinical investigations, owing largely to the present unreliability of the method.

New methods are being worked out in our laboratory to obtain a more reliable determination of muscle excitability. It should be stressed, however, that even if the method could be made reliable, chronaxia would give information only as to the status of the muscle at a certain time. In other words, chronaxia measures a certain condition which the muscle is in at a certain time but not its actual physiologic function. Action currents, on the contrary, are an expression of actual physiologic muscle function. Chronaxia then could be of value if used in combination with action current recordings, provided that the technic of chronaxia measurement could be made reliable.

# MODES OF SPREAD OF INFANTILE PARALYSIS

At the conference of the Federation of Sewage Works Associations in Chicago in October Maxcy and Howe reviewed the significance of the occasional presence in sewage of the virus of infantile paralysis. The demonstration of the virus in the stools of patients and of carriers has been supplemented by the finding of the virus several times in urban sewage in periods of maximal incidence of the disease. This observation at once raised the question whether the virus in sewage can make its way into water supplies for drinking and for swimming pools and thus perhaps spread the disease. Maxey and Howe point out that the virus can live only a short time in sewage so far as known now and that there is no likelihood of its surviving the passage through water purification plants. There is no evidence at hand that the virus can live on or multiply in water. Maxcy and Howe stressed the fact that infantile paralysis does not behave like a water-borne disease. It has not been "correlated with poor water supplies nor have explosive outbreaks of widely scattered cases." appeared in cities with municipal water systems, which would be expected to occur if virulent virus was disseminated in the water mains. Cities with water supplies remote from human abodes suffer from infantile paralysis as frequently as cities whose water comes from sewage-polluted sources. Indeed, the epidemic spread of the disease has been quite independent of common water supplies. There is no record of any explosive outbreak of infantile paralysis attributable "to simultaneous exposure of a group of people to a common source of water." Consequently it seems safe to conclude that the presence under certain circumstances of the virus of infantile : significance as far as the is concerned.

Maxcy and Howe consider also the transmission of infantile paralysis by flies and by personal contact. The virus has been demonstrated in flies in epidemic areas, but flies are not invariably associated with the disease and the disease would not "attack children preponderantly, as is the case, were it transmitted primarily by the fly or any other insect." How about the patient himself and the carrier as sources of infectious virus? In both the virus is present in the stools, the secretions, and the walls of the pharynx; hence it can pass to other persons by means of fecal contamination of the hands, food, milk, and other objects as well as by droplets of pharyngeal mucus.

Present knowledge points to contact infection as the most important means of spreading infantile paralysis. This being the case, everything in human power must be done to prevent contact infection. Unquestionably there is need now for closer isolation than has been carried out in the past. The discovery of practical methods for detection of the virus and for determination of infectiousness on the part of the patient and of potential carriers is a task for the future, not to mention the possibility of finding means to hasten the destruction of the virus in the human body.—J.A.M.A.

have been related to the profession during the past three years.

All of us are aware of the many significant discoveries that have been made in the recent past. This is to be credited to two causes: (1) the organization and direction of the National Foundation, Incorporated, under Mr. Basil O'Connor, as President, and Dr. Don W. Gudakunst, as Medical Director, and (2) the fact that the research work of the National Foundation was based upon all that had been learned about infantile paralysis since 1784 when Michael Underwood was credited with the earliest recognition of the disease.

There is only one reason why infantile paralysis provokes fear and that is because the disease is known to be followed by muscle weakness or paralysis. Until 1940 the cause of this effect was generally agreed upon. It was first explained by G. Meden in 1887 on the basis of pathologic changes found in and related to the motor neurons of the spinal cord. This point of view was closely associated with the classical work of Ivar Wickman as published in 1909. Wickman is credited with first raising the question of the point of entrance. the method of infection, and the spread of the virus. As related to the then current discussion, he stated that the essential points to be determined are: "First, why the malady which from a pathological standpoint is a strictly localized affection, develops clinically as a systemic disease; and second, why the effects are limited practically to the anterior horn and are not distributed as in a transverse myelitis." As to portal entry in human beings, it was his belief that, "infection takes place by way of the alimentary canal." He further regarded "the spread of the virus from the site of inoculation especially by way of the nerves: the infection extending along the lymphatics which accompany the nerves."

In 1912, Peabody, Draper, and Dochez\* examined autopsy material from eleven human patients who died during the acute stage of infantile paralysis. They found practically constant occurrence of "lesions in the posterior ganglia. The histological changes are similar to those that take place in the cord itself . . . . . These lesions in the sensory ganglia may in part account for the pain which is such a constant feature of the acute stage of the disease. Another element in the production of pain is the cellular filtration which is found along the nerve roots."

The volume of work done on the subject of infantile paralysis was indicated by the critical analysis of more than 8,000 references, representing the report of the International Committee published in 1932, under the direction of Dr. W. H. Park. From this and other sources one learns that evidence of the direct and indirect effect of the virus has been shown to prevail throughout numerous levels of the nervous system, the lymphatics, and other structures. But, despite the side distribution of pathologic changes previously defined and more recently revealed, pain, when present, is usually

limited to a few weeks while muscle weakness or paralysis does not always occur, and when it is present it is almost always followed by improvement for six months or longer following onset, despite the mode of treatment employed. Recognition of these well-established facts further intensifies the difficulties of drawing valid conclusions on the results of one method of treatment versus another, particularly when the dominant evidence of developing deformities is usually presented by patients in the chronic stage about two or more years after onset.

In referring to the absence of correlation between the clinical symptoms and the pathologic findings Dr. Gudakunst has stated that the picture is indeed a complicated one. This is probably why Wickman gave the following classification in 1911: (1) ordinary paralysis—anterior poliomyelitis; (2) progressive paralysis—Landry's paralysis; (3) bubar paralysis—polioencephalitis of the pons; (4) acute encephalitis—giving spastic paralysis; (5) atoxic type; (6) meningitis type; (7) polyneuritis type; and (8) abortive type

But it must again be emphasized that the permanent functional limitations that characterize the disabilities of infantile paralysis are characteristically limited to the skeletal muscles.

As to treatment, the principle of rest in the treatment of disabled extremities is instinctive in animals and man. It is truly a part of the Kenny method of treatment. But here we are concerned more with the Kenny concept of spasm as a cause of dysfunction in muscles as against flaccid paralysis, while at the same time the Kenny concept does not preclude the possibility of a true paralysis occurring as a result of massive destruction of anterior horn cells.

The author has given us a clear statement of Miss Kenny's concept of spasm as she finds it to prevail in voluntary muscle and her regard for spasm as the prominent and important symptom. Miss Kenny further believes that spasm is directly, or indirectly, responsible for most of the symptoms—i.e., pain, tenderness, and contraction. Miss Kenny goes further: she believes that the stretching of a muscle by a spastic antagonist can cause the stretched muscle to lose its power of contraction.

Because these views, advanced by Miss Kenny, have come from her experience as a nurse, Dr. Gudakunst and the Advisory Committee of the National Foundation for Infantile Paralysis, Incorporated, recognized the need for investigations, based on established laboratory methods, for determining the neuromuscular reactions of patients during the acute stage of infantile paralysis.

Dr. Bouman's paper represents the results of such an investigation. Therein it was revealed that muscle spasm is much more widespread throughout the voluntary muscles than Miss Kenny originally believed. All information thus far acquired from such investigations is the result of the clinical application of principles developed in physiologic laboratories and expressed by the incorporation of special features in the combination of four action-current amplifiers and the multiple recording oscillograph.

While affording an opportunity for Miss Kenny to

<sup>\*</sup>Monograph No. 4, Rockefeller Institute for Medical Research, New York, 1912, p. 22.

The spermatic specimen is obtained from the proper donor (or husband, as the case may be) in the office, by manual manipulation and is ejaculated into a sterile 25 cc. glass beaker. If this material is permitted to stand for about five minutes, its consistency becomes less viscid and it is more easily aspirated into the 5 cc. syringe. The potency of the spermatozoa is not materially altered. The introduction of the entire amount into the cup is facilitated by the use of the "extension."

The anterior rim of the contraceptive diaphragm is pried away from the anterior vaginal wall with the left index finger. It is important not to dislocate the diaphragm from the posterior fornix, which is its fixed point posteriorly. With the right hand the syringe is held so that the extension is introduced into the cup. The entire amount of the ejaculate is injected into the cup, and the diaphragm is permitted to go back into place (Fig. 2). The anterior rim is pushed behind the symphysis pubis to make it secure. The patient is permitted to get up immediately. The diaphragm is not removed for twenty-four hours. The patient is warned not to douche.

Fig. 2. Schematic drawing of the technic of artificial insemination with the aid of a contraceptive diaphragm.\*

This procedure of insemination is repeated three times; on the twelfth, fourteenth, and sixteenth days after the beginning of the menstrual period, as a rule.

The major advantages of this procedure are.

- 1. It does not produce any trauma.
- Prolonged contact of the spermatic specimens with the cervical canal is insured.
- 3. The vaginal diaphragm reduces the volume of the space within which the small amount of spermatic fluid is kept confined by its proper fitting where it can do most good. There is no loss of fluid by leakage or absorption by tampons.
- 4. The diaphragm actually lifts the cervical os away from the posterior vaginal wall so as to enhance the possibility of insemination.

5. The entire procedure is simple and without danger of infection if carried out properly.

6. Its most important asset is the probability that it will reduce the time and the number of attempts necessary for successful artificial insemination.

The author wishes to report four consecutive successful inseminations in cases that were definitely proved to require this procedure. In fact, the husband was used as donor in three of the four cases and a suitable donor was used in the case reported. In the first two cases, spermatic fluid was introduced into the cervical canal with the help of a flexible cannula and extension (Fig. 1).

The cannula shown in Fig. 1 has the advantage of not being occlusive and, at the same time, of being atraumatic. Successful results were obtained with the two cases in three monthly attempts. The diaphragm method was used in the last two cases. Successful results in both of these cases were obtained in two months and in one month, respectively.

# Summary

A method of artificial insemination using the vaginal diaphragm is suggested.

The method is simple to perform, is nontraumatic, and lends itself to more extensive use as indicated.

#### Discussion

Dr. I. C. Rubin, in his discussion of this report when it was presented at the New York Academy of Medicine, pointed out that he had made the following comment in 1933: "Great care should be exercised in injecting of the spermatic fluid; much pressure must be avoided, as the semen can be introduced into the tubes and out into the peritoneal cavity, resulting in peritoneal irritation and pelvic inflammation.

This artist's drawing was made available to me through the kindness of the gynecologic division of Julius Schmid. Inc. —Author

# ARTIFICIAL INSEMINATION AIDED BY THE USE OF THE VAGINAL DIAPHRAGM

Borris A. Kornblith, M.D., F.A.C.S., New York City

NUMBER of critical reviews of the subject  $\Lambda$  of artificial insemination have appeared recently. The reports of Alan F. Guttmacher in the Bulletin of the New York Academy of Medicine of August, 1943, and another by Clair E. Folsome in the American Journal of Obstetrics and Gynecology of June, 1943,2 are very complete. These take up fully the discussion of the various aspects of this subject, such as the indications for the procedure, the selection of suitable cases, the selection of a homologous or heterologous donor; the psychologic aspects, sociologic consequences, religious considerations, and medicolegal aspects, of this procedure. There is little unanimity of opinion regarding any of these phases, and each one has stirred up some acrimonious discussion in the recent literature.3.4 There is one point upon which all, even the most critical, agree, and that is that "artificial insemination as a means to overcome sterility in the barren couple, wherein the male is principally at fault, is a medical procedure valuable only as a final answer in certain carefully selected and thoroughly studied cases."2

Artificial insemination as a method of overcoming sterility has been widely used. 1,5 It is noteworthy that the exact technic employed up to the present has not been described in detail and that the methods used have been left to the ingenuity of the individual physician. The result has been the utilization of various larger or smaller rigid metal or plastic cannulas which are likely to traumatize the cervical canal or endometrium the moment they are introduced with the specimen. This may account for some of the failures encountered. Until now between twelve and twenty-one attempts at insemination were necessary before a pregnancy resulted in the majority of successful cases. 6

Since the concept is apparently sound, any method which may make the technic easier and possibly reduce the time necessary for successful insemination deserves further trial. With this in mind, the following method is suggested. It is not the province of this communication to intrude upon the other more complex issues involved in the problem of artificial insemination.

### Equipment

The necessary equipment consists of the following sterile set (Fig. I):

Presented before the Section of Obstetrics and Gynecology of the New York Academy of Medicine, October 26, 1943.

- A. A Luer syringe, 5 cc. The standard syringe will do, but a Luer-Lok syringe is preferable to avoid a possible dislocation of the unit and loss of the specimen.
  - B. A Luer needle extension.
- C. A special silver needle (cannula) with bulbous point.
  - D. A glass beaker, 25 cc.
  - E. A vaginal diaphragm.

# Technic

The patient is placed in the dorsosacral (lithotomy) position. A vaginal speculum is introduced and the cervix is wiped clean with dry absorbent cotton. The cervical canal is then cleaned out with sterile applicators, and the mucqus plug is wiped out as much as possible without injuring the cervical canal. The speculum is then removed and a properly fitting, previously boiled, vaginal diaphragm is introduced. Boiling removes any chemical irritant or powder from the rubber. The cupped side faces cephalad so that the cervix will be confined in the concave aspect and be bathed in the pool of spermatic fluid which will be introduced into the cup. The diaphragm is left in place for about ten minutes in order to assume body temperature. This will reduce the factor of injury to the spermatozoa because of temperature differences. During this period, the diaphragm becomes coated with the vaginal secretions and thus reduces the amount of direct contact of the spermatozon with the uncoated rubber.

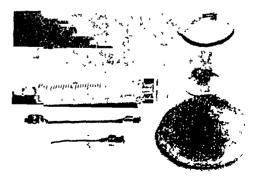

Fig. 1. A. B-D Yale Luer-Lok No. 5YL—5 cc. B. B-D Luer needle extension (Luer-Lok Slip to Luer-Lok Slip LLX—2½ inches). C. B-D Special silver needle (cannula)—bulbous point ½ inches, 43 LAC. D. Glass beaker—25 cc. E. Standard contraceptive diaphragm.

# FEVER AS AN ADJUVANT TO SPECIFIC THERAPY IN SYPHILIS

Evan W. Thomas, M.D., New York City

THE use of fever as a uncraped of far back in history. Bierman' in an interesting THE use of fever as a therapeutic agent dates paper has traced the use of hot baths and other fever-producing agents among the Egyptians and ancient Greeks as long ago as the fifth century B.C. Hot vapor baths and hot mud holes were used by the American Indians in the treatment of disease, and Bierman quotes many other instances of the empirical use of fever in prescientific medicine. The combination of heat and mercury was widely used during the seventeenth century in treating all types of syphilis. In numerous instances fumigations with mercury in an oven were probably more injurious to the well-being of patients than syphilis would have been, but there is little doubt that this treatment checked the progress of the syphilitic infection.

As medicine became more scientific and the toxic effects of heat and mercury were generally recognized, the use of heat in the treatment of syphilis was abandoned and for all practical purposes entirely forgotten for many years. In the eighteenth century the medical profession regarded fever as a dangerous symptom. As a result, antipyretic drugs became one of the most popular weapons in the physician's armamentarium and continued to be until relatively recent

About the year 1870 Pfluger and Wunderlich attempted to stress the possible physiologic value of fever in fighting infections, but it was not until the second decade of the present century that the use of fever as a therapeutic agent received popular recognition in modern medicine. was largely due to Wagner-Jauregg's success with malaria in the treatment of general paresis.

Wagner-Jauregg's interest in fever as a therapeutic agent started in the nineteenth century. In 1887 he published his first paper on "The Influence of Fever-Producing Diseases on Mental Disorders."2 Among the authors quoted in this article was Kiernau, an American physician, who in 1884 published a report on the remissions of mental disorders in patients who acquired small pox in a New York City asylum. Prior to his success with malaria in treating general paresis, Wagner-Jauregg experimented for many years with numerous fever-producing agents. Although he originally thought of malaria, he hesitated to

use it because of the possible dangers involved in its relapsing characteristics. Consequently in the early years of his experiments he tried erysipelas, then tuberculin and typhoid vaccines. It was not until 1917, when he had already decided that patients suffering from general paresis were the most likely to be benefited by fever, that he turned to malaria. The striking results obtained with this therapy in paretics won the Nobel Prize for Wagner-Jauregg. Since that time the use of fever has been widely adopted and has come to be recognized as the most valuable weapon now available in the treatment of meningo-encephalitis due to syphilis.

Probably because Wagner-Jauregg approached the use of fever from its observed effects on mental disorders and because he originally reported its use only in cases of general paresis, most physicians gained the impression that only cases of general paresis or so-called parenchymatous neurosyphilis were suitable for fever therapy. This idea is still far too prevalent among syphilologists. As far back as 1919 Dattner,4 in Wagner-Jauregg's clinic in Vienna, began to treat types of neurosyphilis other than general paresis with fever therapy. He and others have now established its value in all types of neurosyphilis, and there is reason to believe that fever has an important place in the treatment of all stages of syphilis.

# The Rationale of Fever Therapy in the Treatment of Syphilis

The reasons for the benefits of fever in the treatment of neurosyphilis have been the subject of much speculation. In the space allotted to me it is impossible to review the literature on this most interesting problem. Suffice it to say that the solution must be sought along two general lines of investigation: (1) the physiologic effects of fever in the host which make for increased resistance to the syphilitic virus and (2) the direct effect of heat on the Spirochaeta pallida. In all probability both of these factors are important in explaining the beneficial effects of fever in syphilis.

With respect to the first factor, investigation of the physiologic effects of fever in the host must be conducted from at least two points of view: (1) the physiologic effects of high temperatures. regardless of how they are induced, and (2) the immunologic reactions and altered sensitivity of cells due to foreign proteins or infectious agents which produce fever. It is well known that high

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 6, 1943.

Department of Dermatology and Syphilology, New York University College of Medicine, and the Department of Dermatology and Syphilology, Third Medical Division (New York University), Bellevue Hospital, New York City.

When this is feared, the fresh semen can be transferred into a rubber cervical cap and the latter fitted over the cervix for twenty-four hours."7

Dr. Robert L. Dickinson discussed early methods of artificial insemination and the difficulties encountered in attempting to retain seminal fluid in the cervical canal. He also drew attention to the mechanism of ascent of spermatozoa into the uterus as described by Kolbows-i.e., that when fluid is present in the posterior fornix, the vaginal wall shows intrinsic contraction which lifts the pool of fluid up against the cervical os. This would prove to be an argument in favor of the method described.

### MOLDS MAKE ANALYSES

Molds that can outdo skilled chemists at one special and difficult job of analysis were the strange creatures introduced to the American Chemical Society at its meeting in Pittsburgh, by Dr. Erwin Brand of Columbia University.

The task at which these humble but biochemically sensitive plants have worked is the accurate determination of the concentration of one of the building blocks of protein in extracts of several protein varieties. With their aid it has been possible to make such determinations in a few days, whereas by previously existing methods a whole corps of highly trained chemists would have to work for months to achieve an equally accurate outcome.

The story begins with the creation of special physiological races of a red mold, botanically known as a Neurospora, in the laboratories of Dr. George W. Beadle at Stanford University. By x-ray treatment, a parent strain was induced to undergo evolutionary changes. Pure lines of descent of these new races were assured by isolating single reproductive spores and growing small "gardens" of mold from each one.

Some of these strains were physiologically very choosy. They required one kind of amino acid, one of the building blocks of protein, and would not grow without it. One of the strains had to have the amino acid known as leucine. This is the one that Dr. Brand used in his researches.

Grown on nutrient preparations of various pro-teins, this "minus-leucin" strain of mold would develop a certain amount of weight for each per cent of leucin present in its food. Then it would stop. After giving it time enough to reach full growth, Dr. Brand and his associates would harvest the mold, dry and weigh it, and thus learn immediately what would otherwise have taken months of tedious toil.

The practical value of this kind of research is very great, but it will take years of continued effort to develop it fully. Protein analysis is one of the most difficult of all chemical jobs, yet it is important for such work to be done because proteins are not only the stuff our muscles are made of but also many of the other important though less bulky constituents of the body, and many of the poisons that make us ill and the medicines that make us well. Snake and spider venoms are proteins, and also insulin and all the physiologically important gland extracts. So there is plenty of work ahead for both the chemists and their specially bred molds, for a long time to come. - Science News Letter

# MEDICAL WRITING UNDER DIFFICULTIES

The first issue of the Chinese Medical Journal, January-March, 1943, since Pearl Harbor has just made its appearance. The official organ of the medical profession in China is published in Chinese for circulation in Free China, and in English in the United States with the aid of the China Foundation. That a creditable journal, and indeed it is a very creditable one, could be produced under the diffi-culties that now exist in China is truly remarkable. Most of the larger and better medical institutions in occupied territories have been closed. Many of the medical schools have been moved into Free China, but at a tremendous loss of equipment, supplies, and teaching personnel. The editor calls attention to the fact that writing in a foreign language without the necessary well-equipped hos-

pitals and laboratories in which to work and without proper library facilities is not productive of an overabundance of first-class articles. He says nothing of the difficulty of printing and publishing the Journal on the other side of the world, but promises to do his best to uphold the high standards that the Chinese Medical Journal has always had. The "News and Notes" gives additional evidence, if any be needed, of the difficulties with which our Chinese conferrs have to contant. Chinese conferers have to contend. For instance, in Shanghai, where it seems the Chinese doctors are carrying on with their practices in spite of numerous emergency obstacles, Dr. W. S. Fu has borrowed a tandem bicycle. The doctor rides on the back seat while his former chauffeur pedals and steers in front.-Virgina Medical Monthly

# Fever as an Aid in the Rapid Treatment of Early Syphilis

It is not within the scope of this paper to recapitulate the recent history of attempts to cure early syphilis within a period of a few days or weeks. Numerous thousands of patients with early syphilis have now been treated by various modifications of the method first introduced by Chargin, Leifer, and Hyman. For the best results, if treatment is to be confined within a period of from five to ten days, a total of at least 1 Gm. of arsenoxide must be administered either by an intravenous drip or by multiple injections. From available statistics the incidence of arsenical encephalopathy with this dosage is about 1 per cent. The incidence of deaths in reported series has been about 0.3 per cent.

In the hope of lowering this incidence of serious reactions in 1940 at Bellevue Hospital, we decided to combine fever with mapharsen. This was done originally with the intention of killing two birds with one stone. We hoped that fever would protect patients against toxic reactions and that it would enable us to achieve good therapeutic results with a lower total dosage of mapharsen. As far back as 1923, Kyrle<sup>10</sup> suggested that fever decreased the toxicity of arsenical drugs. In 1940 de Krief and Simpson<sup>11</sup> made the same assertion. Our own experience with the intensive use of mapharsen following malaria in cases of neurosyphilis led us to believe that fever might protect patients against arsenical reactions of the cerebrospinal axis.

Actual experience with fever combined with intensive mapharsen therapy in early syphilis failed to confirm the impression that fever protects against reactions to arsenical drugs, nor have we been able to prove that fever has any protective effect against the toxicity of mapharsen in rabbits. Dr. Goldstein and his coworkers in the New York University College of Medicine have run large series of rabbits, giving the same amount of drug in daily injections to controls and to rabbits with induced fevers. Fever failed to protect the rabbits that were given toxic doses.

We have proved to our satisfaction, however, that by combining fever with mapharsen the same therapeutic results can be achieved with about half the total amount of mapharsen that is required when fevers are not used. At Bellevue Hospital we have now treated 1,280 patients with early syphilis with various methods of rapid therapy. Over 950 of these have been treated with some combination of fever and mapharsen.

Fever was induced in 890 cases by the intravenous injection of typhoid vaccines.

Two injections of vaccine were usually given on the days when fever was desired. It is true that typhoid vaccine is not an ideal pyrogenic agent, but in a busy service it has proved the most practical means available of inducing fever when patients are receiving mapharsen as well. With this treatment the patients suffer from varying amounts of discomfort, but in our entire series of cases no serious accidents attributable to the use of typhoid vaccines occurred.

Our present plan of treatment, adopted since our latest report, 12 consists of ten daily injections of about 0.06 Gm. of mapharsen combined with fever induced every other day by typhoid vaccines. Thus each patient receives about 0.6 Gm. of mapharsen and 4 fevers in a ten-day period. This plan of therapy has been in effect since July, 1942, and so far has proved very satisfactory. It is interesting, though by no means statistically significant, that the highest percentage of patients achieving satisfactory results after one year or more of observation occurred in a group which received 4 fevers induced by typhoid vaccines and only 0.54 Gm. of maphar-The number of treatment failures among patients receiving less than 0.8 Gm. of mapharsen alone was significantly higher than it was when fevers were combined with even smaller total dosages of mapharsen, 22 and 14 per cent, respectively.

Thus our experience confirms the earlier evidence that fever is an important aid in the therapy of early syphilis. The fact that relapses were no more common among patients who had rather poor fevers with typhoid vaccines than among those who had temperatures up to 106 F. suggests that it is not the height of the temperature alone that influences the eradication of the syphilitic infection. This may be another argument in favor of the theory that it is the physiologic effect of fever in the host which is more significant than the direct effect of high temperatures on the spirochete. That this is not due to the action of foreign protein is suggested by the fact that electropyrexia when combined with mapharsen produces as good or better results than fevers induced by typhoid vaccines.

# The Effect of Combined Fever and Intensive Mapharsen Therapy in Neurosyphilis

That fever permits a more intensive and briefer course of chemotherapy in the treatment of neurosyphilis than is generally realized has been proved by our experiments in the rapid treatment of active neurosyphilis at Bellevue Hospital. As previously reported<sup>13</sup> our plan of therapy in neurosyphilis includes 8 fevers induced by malaria or electropyrevia followed by ten daily injections

temperatures, however induced, increase the oxidative process of the body. Less is known about the physiologic effects of fever in altering tissue reactions. For example, whether high temperatures influence the reticulo-endothelial system to any significant degree is still questioned.

158

It is quite probable, however, that elevation of the body temperature has other more significant effects than the increase of metabolism.

When we turn to the immunologic and the physiologic changes caused by the introduction of fever-producing infections and foreign proteins, we are still more in the dark. Speculation is of little value on this point until our understanding of the physiology of cells and immunology in general is increased.

Recent reports of the beneficial results of fever induced by physical means seem to indicate that hyperthermia alone is able to produce physiologic changes which enable the body to combat the syphilitic virus, or else we must assume that S. pallida are injured solely by the direct effect of the increased temperature. As will be seen later, this latter assumption is subject to considerable doubt. Until recent years most authorities favored the use of malaria in the treatment of neurosyphilis partly because of the impression that the malarial plasmodia had other beneficial effects in overcoming the syphilitic virus than the mere production of high fevers.

There is no proof that this is true in any way, but it is still too early to jump to conclusions about the relative merits of malaria and mechanically induced fever in the treatment of neurosyphilis.

More accurate information on this point is needed than is now available. Not only must we have large series of comparable cases treated similarly, except for the manner in which fever is induced, but we must also have commonly accepted scientific criteria for evaluating the results of therapy before we can adequately compare different types of fever therapy which are already known to be of benefit. The formulation of criteria for evaluating treatment in neurosyphilis is easier than in cardiovascular syphilis or late latent syphilis because of the aid accorded by spinal fluid examinations. Until we make the most of the various spinal fluid tests which should be easily available, the evaluation of therapy in neurosyphilis will continue to be largely subjective rather than scientific.

There is no question, however, that fever produced by any means that is tolerated by the patient has a beneficial effect in the treatment of syphilis. The explanation of this fact awaits further enlightenment.

# Experimental Data on the Spirocheticidal Effect of Fever

It has long been an accepted fact that it is easier to cure syphilis in the early stages than later on. Consequently, if prolonged fever at temperatures which are reasonably safe to the patient fail to kill all the spirochetes in primary and secondary syphilis it is unlikely that it will do so in the late stages of the disease. Boak, Carpenter, Jones, Kampmeier, McCann, Warren, and Williams<sup>5</sup> found that temperatures of 41 to 41.5 C. prolonged for nine to fifteen hours caused rapid healing of primary and secondary syphilitic lesions but failed to prevent relapses. Furthermore, darkfield examinations of serum from the lesions remained positive in 3 of their 8 cases for fifty-three hours, four days, and five days, respectively.

Thus in almost 40 per cent of their small series of cases even the spirochetes in surface lesions were not killed immediately by the direct effects of the higher temperature. Because the syphilitic lesions healed and the darkfield examinations finally became negative, we must assume that the fever either increased the resistance of the host to the spirochetes or directly injured them so that most of them died over a period of days after the fever. Those which survived apparently became dormant only to begin to multiply again within 3 to 6 weeks as shown by mucocutaneous relapses with darkfield positive lesions.

Thus it is apparent that a single session of fever prolonged to the point of tolerance by the patient will not kill all the spirochetes in humans with early syphilis and does not always cause prompt destruction of spirochetes even in surface lesions.

Experimental work has shown that prolonged high temperatures are more successful in curing early syphilis in rabbits than they are in human beings, but even in rabbits such treatment is effective in only a small percentage of cases. Boak, Carpenter, and Warren<sup>6</sup> reported successful cures of early syphilis in rabbits with a single session of six or seven hours of fever in only 4 of 38 rabbits treated. They found, however, that when subcurative doses of arsenical drugs were combined with only three or four hours of fever. 42 out of 43 rabbits were cured. In man, Richet and Dublineau, in 1933 and Simpson, in 1935, found that when fever was combined with relatively small amounts of arsenical drugs early Eagle's8a experiments syphilis could be cured. with the spirocheticidal action of arsphenamines in vitro lend at least partial experimental support to the clinical observation that increased temperature enhances the therapeutic effect of antisyphilitic arsenical drugs.

proved a relatively safe therapeutic procedure at Bellevue Hospital, where the shortage of nurses precludes much individual attention to patients. Malaria should not be attempted in patients with cardiac decompensation but if there is no circulatory failure even cases of aortic insufficiency can be given malaria without undue danger, provided the patient is in good physical condition otherwise. Fever should not be attempted in patients with tuberculosis.

The use of electropyrexia in our experience is relatively safe provided fevers of over 105 F. are not prolonged beyond five or six hours. The risk of temporary but dangerous kidney damage, expecially when mapharsen is given during the fever, is considerable when high temperatures are prolonged beyond six hours. In a series of 48 cases of early syphilis treated over a twoday period with two injections of about 0.06 Gm. of mapharsen during the first day and seven hours of electropyrexia the following day, with two additional injections of 0.06 Gm. of mapharsen, 4 patients developed an acute nephrosis with uremia lasting over a period of from ten to twenty-one days. An additional 4 developed severe azotemia without fixed specific gravities of the urine. There are practically no reports of this particular complication in the literature of artificially produced fever alone, but from personal communications there is reason to believe that it has occurred. Certainly the combination of mapharsen with prolonged electropyrexia has proved so hazardous with us that it has been completely abandoned. When fevers produced by physical means are not prolonged over five hours, we have observed no noteworthy kidney damage, even when mapharsen was given with the fever.

#### Conclusions

Fever is a valuable adjuvant to chemotherapy in early syphilis and neurosyphilis.

There is reason to believe that it can be equally effective in all types and stages of syphilis where there are no contraindications to its use.

It should be used in all cases of syphilis that prove resistant to chemotherapy unless there are contraindications to its use.

The combination of mapharsen and electropyrexia at temperatures at 105 F. or over for a period of more than six hours may result in a temporary acute nephrosis.

# BASIC ENGLISH IS FOUND NO GOOD FOR BASIC FOLK

Basic English is not suited to the needs of the average person who wants to converse with men and women from other lands, according to Miss Elaine P. Swenson, former director of the New York office of the Language Research Institute.

Miss Swenson, who spoke to the group of teachers attending the tenth annual language conference at New York University, said "attempts to use Basic English in teaching non-English-speaking residents of Hawaii and the Philippines had failed." They were still unable to understand the English spoken by the Americans they came in contact with.

Miss Swenson believes that a person with an I. Q. of less than 120 cannot use Basic English successfully. Because of its limited vocabulary, she explained, most of the 850 words in Basic English must have more than one meaning. average person, she pointed out, is incapable of distinguishing just what is meant.

# DIGESTIVE DISORDERS IN COMBAT AREAS

From experience with 200 patients admitted to a large hospital in the South Pacific because of "dyspepsia," Capt. Alexander Rush, Medical Corps, Fifty-Second Evacuation Hospital, reports in the Journal of the American Medical Association for October 23 that "from a medical point of view the selector who on the besie of his Army coners." selectee who on the basis of his Army general classification test gives indication of being a poor risk has been so proved while under the stress and strain of field conditions in the combat area.

Fifty-three per cent of the patients were found to have functional disturbances of the digestive tract. No organic basis for their distress could be demonstrated. The greater number of these patients were in grades IV and V (slow and very slow learners) in the Army general classification test. This bears out the impression that digestive disturbances of the functional type are seldom seen among bright, alert, well-integrated persons, Captain Rush says .- Illinois, M.J.

of 0.06 Gm. of mapharsen. No further treatment is given unless the spinal fluid of patients shows the presence of increased cells or protein six months after treatment. The full report of the results achieved by this shortened treatment must await a more extended period of observation, but it can already be said that of a total of 194 patients treated in this manner and followed for from six months to three years only about 15 per cent had to be retreated or permanently institutionalized.

It is, of course, true that the more advanced the destructive process in the central nervous system the less clinical improvement can be expected from any therapy. But even in cases with marked mental deterioration or degenerative changes in the spinal cord, the active syphilitic process in the central nervous system as shown by spinal fluid studies can usually be checked by 8 fevers followed by 10 daily injections of 0.06 Gm. of mapharsen. These results not only agree with the well-established effectiveness of fever in all types of neurosyphilis but they prove that relatively intensive and brief chemotherapy immediately following fever is as effective, if not more so, than many months of conventional routine treatment with tryparsamide or bismuth and trivalent arsenical drugs following fever.

Clinical improvement may follow treatment of neurosyphilis with fever alone, as is true in early syphilis, but if relapses are to be prevented, additional chemotherapy is required. The sooner mapharsen is used after fevers and the more intensively it is given, the better the results are likely to be. When fevers are induced by mechanical means, mapharsen can be given with the fever and on intervening days. When malaria is used, arsenical drugs must be withheld until the fevers are stopped because they have an inhibiting effect on the malarial plasmodia.

# The Use of Fever in Late Syphilis with Negative Spinal Fluid

Very little statistical data are available as to the effect of fever in late latent or other types of late syphilis with negative spinal fluids. There is every reason to believe, however, that it should be as effective in such cases as it is in neurosyphilis. Kaplan,14 in November, 1939, inaugurated a long-range program in the rapid treatment of late syphilis among the inmates of New York State prisons. Some of his patients with late latent syphilis have received combined fever and mapharsen therapy. The results of this experiment cannot be evaluated for at least several more years. It is unreasonable to expect rapid reversal of serologic tests in late syphilis even though the infection is cured. It is well-known that it may take five years for a

positive spinal fluid Wassermann test to become negative after the completion of successfully treated neurosyphilis. The same is true of the blood tests for syphilis which may remain positive for an even longer period of time in some I have now accumulated a small series of 12 cases of late latent syphilis treated for two years with routine chemotherapy where blood Wassermann tests which were obtained periodically became negative from two to four years after the completion of therapy. There is no reason to believe that treatment prolonged for over two years would have hastened the reversal of the serologic tests in these cases. Thus late cases of syphilis that are treated intensively with combined fever and chemotherapy must be followed for a number of years before the effect of treatment can be even approximately evaluated.

As a rule syphilitic gummas of the skin are easily healed even with bismuth. Therefore, it is not surprising that they respond well to fever. A syphilitic manifestation like interstitial keratitis frequently responds very poorly even to intensive chemotherapy. Fever can be of great aid in the treatment of such cases. At Bellevue Hospital we recently treated a girl, 13 years of age, who had severe interstitial keratitis of the left eye which developed after chemotherapy had been instituted. We gave her a course of 8 malarial fevers, only to have the other cornes become affected. She was then given a course of mercury inunctions with no appreciable improvement, after which she was rehospitalized and given 8 fevers induced by physical means combined with intensive mapharsen. This produced dramatic improvement. Other cases of interstitial keratitis have responded well to a single course of 8 malarial fevers followed by intensive mapharsen.

# Risks Involved in Fever Therapy

Malaria is surprisingly well tolerated in most cases, even by patients who are debilitated and poorly nourished. It is not without its risks, however, and the incidence of deaths has been as high as 12 per cent in some institutions where it has been used extensively. The longer the course of fevers the greater the risk. Dattner15 has shown that 8 fevers will produce as good results in neurosyphilis as more prolonged courses and the risks to the health of the patient increase with the number of fevers. Consequently, it is a mistaken policy to prolong the course of fevers beyond 8 or 9. Even so, occasional instances of jaundice, usually hemolytic, will be encountered, and poor nursing care may result in pneumonia when patients become chilled during the profuse sweats which follow the fevers. On the whole, however, malaria has

life of the individual who may be, at the moment, a patient under treatment. It is employed as a remedy; i.e., (a) to mitigate symptoms (local and general), (b) to shorten the duration, and (c) to diminish progression, extension, and sequelae. It seems to be useful in all these categories.

A report on the first 60 cases was prepared and filed in the office of a medical society, but withheld from publication for over a year because of the importance of the matter, the lack of any important parallel of results in the literature, and the general doubt, shared by the writer, of the values of any vitamin as a remedy in this field. During this time, although no duplication of the method has appeared as yet, parallel data have been presented and the results of personal experience continue to confirm the original observation.

## Rationale and Results

;

Z

ئرې

3

· 子 · 中かかか

The initial reason for the use of vitamin A was the personal observation that the visual afterimages were sometimes markedly increased just before prodromal symptoms of a cold (sneezing, notice of drafts, psychokinesia) appeared. This was noted in a study of dark adaptation for military purposes which involved the development of a quick, practical, office method for the estimation of visual purple efficiency. It seemed possible, therefore, that an oncoming cold might be foreshadowed by a reduction of visual purple efficiency, which, in turn, might be due to a vitamin A deficiency or an impairment in vitamin A utilization. It seemed worth while to try the use of large doses of vitamin A to see whether or not oncoming colds might be prevented. cordingly, vitamins A and D as they occurred in rod-liver oil concentrate were given to a series of patients who had had recurrent colds for years and who knew the preliminary symptoms. It seemed to be helpful. The routine was also employed in cases in which the cold was fully and unmistakably established. The results were still good. Many patients learned to look for a "cure" within twenty-four hours. The routine was also tried in acute sinusitis and bronchitis, the results of which will be referred to later.

It seemed, however, that the most favorable results were obtained by the employment of this routine in the prodromal stage; next, in the early course of acute illness; and last, in the course of chronic illness. The most striking results, however, were obtained in well-established, acute colds that, in 30 per cent of the patients, appeared to be "cured" in less than twenty-four hours.

The reason for using a large dose on the first day, a smaller dose on the second day, and a medium dose on the third day is as follows: A

large dose, 150,000 units of A, was used for "shock" effect. This is an old but until recently a little-noted principle in medicine. It has the nature of a surprise attack, obviating the "tolerance to remedy" occasionally generated by initial small doses. No proof of the validity of this theory is offered. However, it works. No harm results. Moreover, the initial dose has recently been stepped up in secondary trial routines. An initial dose of 2,000,000 units of vitamin A has been suggested.

The second day's dose was lowered to 50,000 units of A in accord with another principle sometimes employed in medicine: that of rhythm or alternation of remedy, commonly employed in cystitis (in change of urinary pH) and in endocrinology.

The most characteristic result is a rapid decrease of both local and general symptoms. In twenty-four hours, sneezing, composition, discovered fort, pain, and discharge sometimes abate or disappear entirely. General malaise, fever, and pain may decrease markedly. The patient may then feel entirely well, especially if the cold is not a severe one. The approximate status at the end of twenty-four hours of treatment of ordinary uncomplicated colds is as follows:

	Number	Percent-
	of Cases	age
"Cured"	34	30.3
Almost cured	58	51.8
Better	11	9.9
No change	6	5.3
Worse	3	2.7
	112	100.0

There was a tendency to recurrence of symptoms and a resumption of the cold at the end of the next twenty-four hours. This would most frequently occur if the patient resumed his ordinary course of life, exposed himself, and acted as if he were quite well again.

This occurred in a case reported by Leak.<sup>1</sup> A fish peddler had influenza. He was given a large dose of vitamin A hypodermically. He was "well" the next day and, against orders, resumed his occupation of selling fish. The third day he was quite as sick as before.

This recurrence was commonly prevented in the writer's series of cases by ordinary caution and the use of one-third of the initial dose on the second day and two-thirds of the initial dose on the third day.

In about half of the patients who report themselves cured in twenty-four hours, there is a fair return to symptomless bodily vigor. In 30 per cent of them there is a period of vague discomfort for a few days. "It seemed as if the cold con-

# VITAMIN AID IN THE TREATMENT OF COLDS

# A Preliminary Report

C. WARD CRAMPTON, M.D., New York City

# Colds Cause Damage

To the physician who gives health examinations, and cares for his patients in health and illness year after year, the common cold presents a persistent problem. Both treatment and prevention are necessary. This paper is on the subject of treatment. Colds often cause disability and damage and predispose to further illness. For many persons they constitute a major life problem. They diminish national efficiency. At the rate of three colds a year for the average American, there are 400,000,000 for the nation! there is an average of two days lost from work and 50 per cent loss of efficiency for two days more, there is a national annual loss of 1,200,000,-000 work days a year. One can only conjecture as to the average decrease in life efficiency, impairment of happiness, increase in other illnesses. and abbreviation of life which may result from colds.

# Colds Vary

The term "cold" must be clearly understood. It is, however, difficult to define because it refers to a group of upper respiratory illnesses which are most diverse in character. One outstanding characteristic of colds is their variability. They vary in severity from a day of simple nasal turgescence and rhinorrhea to weeks of local congestion, pain, inflammation, with general symptoms of fever and prostration, which may be followed by a longer period of bronchitis or sinusitis. Colds vary (1) in the character of onset, (2) in prodromal symptoms, (3) in the locality of the first symptom, and (4) in their general course.

Epidemic and endemic colds may, however, occur and maintain their typical characteristics as they propagate themselves. For example, a wave of colds may strike New York City and sweep through the population. A recent epidemic began with a "dry throat," and continued with fever and prostration, which was followed by a mild or severe bronchitis. It affected 5 to 10 per cent of the population-and as much as 75 per cent of a single office personnel. This epidemic followed its course through the City and then died out. This was followed in sixty days by a second wave of epidemic colds, which began with sneezing, nasal congestion, and a watery discharge, followed by yellow pus. It proceeded, in many cases, to sinus infections with staphylococcus predominating. Meanwhile, New York

City supplied scattering cases of a variety of endemic colds with micrococcus catarrhalis predominating, or grippe, or colds with streptococcus predominance with their characteristic but divergent symptoms. This process has been repeated year after year with unpredictable variations. It might be studied further with profit.

With this diversified character of colds-epidemic, endemic, or casual—any one remedy presented finds itself confronted with a protean enemy as varied in its weapons and choice of attack and terrain as a modern well-equipped army. They all, however, have two common factors: involvement of (1) the mucous membrane of the upper respiratory tract, and (2) the underlying service of supply of the rest of the body upon which the mucous membrane is The presentation of a treatment dependent. under discussion (not a "cure") for colds is, therefore, made with these facts in mind and insisted upon. But it may be confidently stated to have been of use to some people, some of the time. It has been of definite service, however, for more than 103 persons who have used it for more than a year, of whom 32 have employed it for more than two years. They have reason to believe in its efficiency.

The writer has continued its use. Favorable data accumulate, and there is in plan or in process a more extended research, observation, and record in the diverse, closely related clinical and scientific fields. This report is confined, however, mainly to a simple statement of clinical results of three years of experience, with a few references to the more pertinent data from the vast and various related fields of research.

# Remedy and Dosage

The original routine used (begun in 1940 and still continued for the majority of cases) calls for 150,000 units of vitamin A with 15,000 of vitamin D as cod-liver oil concentrate the first day, divided into three equal doses. (The use of other split or synthetic vitamins A and D are not reported upon at this time.)

The second day, 50,000 units of A and 5,000 of D are taken. If any symptoms remain, the third day 100,000 of A and 10,000 of D are taken. The routine may be repeated, but the further continuance of the remedy is very seldom employed and seldom reported on by patients. This prescription is never given alone. It is only an element in a program of management of the

life of the individual who may be, at the moment, a patient under treatment. It is employed as a remedy; i.e., (a) to mitigate symptoms (local and general), (b) to shorten the duration, and (c) to diminish progression, extension, and sequelae. It seems to be useful in all these categories.

A report on the first 60 cases was prepared and filed in the office of a medical society, but withheld from publication for over a year because of the importance of the matter, the lack of any important parallel of results in the literature, and the general doubt, shared by the writer, of the values of any vitamin as a remedy in this field. During this time, although no duplication of the method has appeared as yet, parallel data have been presented and the results of personal experience continue to confirm the original observation.

### Rationale and Results

The initial reason for the use of vitamin A was the personal observation that the visual afterimages were sometimes markedly increased just before prodromal symptoms of a cold (sneezing, notice of drafts, psychokinesia) appeared. This was noted in a study of dark adaptation for military purposes which involved the development of a quick, practical, office method for the estimation of visual purple efficiency. It seemed possible, therefore, that an oncoming cold might be foreshadowed by a reduction of visual purple efficiency, which, in turn, might be due to a vitamin A deficiency or an impairment in vitamin A utilization. It seemed worth while to try the use of large doses of vitamin A to see whether or not oncoming colds might be prevented. Accordingly, vitamins A and D as they occurred in cod-liver oil concentrate were given to a series of patients who had had recurrent colds for years and who knew the preliminary symptoms. seemed to be helpful. The routine was also employed in cases in which the cold was fully and unmistakably established. The results were still Many patients learned to look for a "cure" within twenty-four hours. The routine was also tried in acute sinusitis and bronchitis, the results of which will be referred to later.

It seemed, however, that the most favorable results were obtained by the employment of this routine in the prodromal stage; next, in the early course of acute illness; and last, in the course of chronic illness. The most striking results, however, were obtained in well-established, acute colds that, in 30 per cent of the patients, appeared to be "cured" in less than twenty-four hours.

The reason for using a large dose on the first day, a smaller dose on the second day, and a medium dose on the third day is as follows: A

large dose, 150,000 units of A, was used for "shock" effect. This is an old but until recently a little-noted principle in medicine. It has the nature of a surprise attack, obviating the "tolerance to remedy" occasionally generated by initial small doses. No proof of the validity of this theory is offered. However, it works. No harm results. Moreover, the initial dose has recently been stepped up in secondary trial routines. An initial dose of 2,000,000 units of vitamin A has been suggested.

The second day's dose was lowered to 50,000 units of A in accord with another principle sometimes employed in medicine: that of rhythm or alternation of remedy, commonly employed in cystitis (in change of urinary pH) and in endocrinology.

The most characteristic result is a rapid decrease of both local and general symptoms. In twenty-four hours, sneezing, congestion, discomfort, pain, and discharge sometimes abate or disappear entirely. General malaise, fever, and pain may decrease markedly. The patient may then feel entirely well, especially if the cold is not a severe one. The approximate status at the end of twenty-four hours of treatment of ordinary uncomplicated colds is as follows:

	Number	Percent-
	of Cases	age
"Cured"	34	30.3
Almost cured	58	51 S
Better	11	9.9
No change	6	5.3
Worse	3	2.7
	112	100.0

There was a tendency to recurrence of symptoms and a resumption of the cold at the end of the next twenty-four hours. This would most frequently occur if the patient resumed his ordinary course of life, exposed himself, and acted as if he were quite well again.

This occurred in a case reported by Leak.¹ A fish peddler had influenza. He was given a large dose of vitamin A hypodermically. He was "well" the next day and, against orders, resumed his occupation of selling fish. The third day he was quite as sick as before.

This recurrence was commonly prevented in the writer's series of cases by ordinary caution and the use of one-third of the initial dose on the second day and two-thirds of the initial dose on the third day.

In about half of the patients who report themselves cured in twenty-four hours, there is a fair return to symptomless bodily vigor. In 30 per cent of them there is a period of vague discomfort for a few day. "It seemed as if the cold continued hidden and symptomless." In the remaining 20 per cent there is a feeling of subnormality which may be marked. In a very few of these the "cold" has been resumed, but not with its initial severity. In the beginning, in all cases a routine of customary (and other) local and general treatment was carried out. As experience accumulated, these precautions were relaxed in part, but never abandoned.

#### Vitamin A

There are reasons, clinical, academic, and scientific, which prompted the thought that vitamin A might be of value as a remedy in acute illness, and later tended to confirm it, despite the fact that the use of vitamins had been generally disappointing in prophylaxis.

At this point brief references to some aspects of vitamin A might be of interest and serve the cause of clarity.

Vitamin A is one of the oil-soluble vitamins. The others are the various forms of vitamin D and the several tocopherols. At present there are reported to be three forms of vitamin A—alpha, beta, and gamma. There are also three forms of carotene, the vegetable precursor. In addition, there are nine related carotenoids. The main forms of vitamin A are C<sub>20</sub>H<sub>21</sub>OH, present generally in the livers of salt-water fish; C<sub>22</sub>H<sub>31</sub>OH, in fresh-water fish [Mutatis mutandis].

This diversity of basic constitution may be in part responsible for the astonishing diversity of reported results of the use of these vitamins.

Vitamin A is available in capsules of up to 25,-000 units for oral use. It is presented with vitamin D (natural or synthetic) in tablet or capsule, also in association with other vitamins. preparation used in this work is a cod-liver oil concentrate which may be purchased in open market. Vitamin A for hypodermic use is not generally available. Vitamin A alone and with carotene for topical application to nose and throat is not yet generally commercially available in this country. In clinical office conditions the writer uses it in three forms, provided by the cooperation of three well-established pharmaceutic organizations. Our experience in the use of carotene and vitamin A to date indicates that (1) it nauseates most patients; (2) it acts as a dye: it will stain the skin, and the mucous membrane may retain the stain for thirty-six hours; (3) our preliminary results in acute and chronic nasopharyngeal conditions are somewhat encouraging and more extended trial will be given.

In this connection medical literature was searched for reports on the use of vitamin A or carotene for infections of the nose and throat. The use of cod-liver oil on the skin as an ointment is fairly well known. A paper by Levinson and

Gabrilovich<sup>2</sup> in a Russian journal was brought to light.

They report on 100 cases in city hospitals, with a similar control group. They were treated by inhalation alone, instillation alone, or the two combined. The control group were treated with aspirin, etc., and standard local medication. In the treated group, symptoms of congestion, discharge, headache, and cough were mitigated. Ninety per cent were cured in the first three days, against seven days for the control groups. Recurrences were less common. The authors believe that carotene acts locally and generally as well.

Freyre<sup>3</sup> reported favorable results from the use of vitamin A oil solution given intranasally (5 drops three times daily) to children with more or less chronic coryza. Freyre believes that the results were very good. Reporting that "The treatment was completely successful in 18 out of 41 cases," he states in effect that "the favorable effect can probably be explained by the protective action of the vitamin A on the epithelium. It can be employed pure or in combination with small doses of vitamin D. Before treatment, it is essential to determine the cause; syphilis, tuberculosis, spasmodic rhinitis, or 'nasal asthma,' and, of course, treat the same." Disregarding these cases, there still remain a large number of children with chronic nasal catarrh. For these the author recommends the local application of vitamin A.

#### Vitamin D

Vitamin D was included with vitamin A originally for three reasons: (1) convenience; (2) the occurrence in cod-liver oil of vitamin A and D together in a proportion of 10 to 1, and the well-known service of cod-liver oil in medicine suggested that there might be a synergy of significance; (3) no valid objection appeared.

Subsequently some work tending to provide confirmatory evidence has appeared. Spiesman administered large doses of the vitamins A and D individually, as well as in combination, to a group of selected patients for three consecutive winters and concluded that "Vitamins A and D in massive doses do not produce immunity to the common cold when given separately. When massive doses of vitamins A and D were given together, 80 per cent of the subjects showed a significant reduction in both the number and the severity of common colds."

Vitamin D as well as vitamin A is a factor in successful treatment of nyctalopia and retinitis pigmentosa, according to A. A. Knapp,<sup>5</sup> Commander, (MC), USNR. More research work on the value of association of oil-soluble vitamins (including the tocopherols) in medicine will be

looked for with great interest. The meager record of the day tends, however, to support the purely theoretic initial approach and the resulting clinical record with respect to use of the natural combination. The use of carotene alone, combinations of carotene and vitamin A, the combination of these with vitamin  $D_1$ , 2, 3 and tocopherols, and the use of much larger doses of vitamin A are in process or plan.

### Other Diseases

Hypertension.—Vitamin A has been offered as a remedy in hypertension by Govea Pena and Villaverde<sup>6</sup> and Walkerlin, Moss, and Smith.<sup>7</sup>

Tuberculosis.—Harris and Harters suggest vitamin A in treatment of night blindness and vitamin A deficiency in pulmonary tuberculosis.

Fifty-three per cent of 197 tubercular patients were physiologically deficient in vitamin A by biophotometric tests, according to Getz, Hillebrand, and Finn.<sup>9</sup>

Whooping Cough.—Rats recover from pertussis if receiving vitamin A, according to McCoord, 10 University of Rochester. McCoord in a personal communication states: "We find that whooping cough and almost anything that produces fever appears to destroy vitamin A in the body. We therefore suggest that persons suffering from such diseases be given extra vitamin A if their illness is long continued."

These observations suggest a tendency toward the possibility of defining the specific service of vitamin A as a remedy.

#### Vitamin B Factor

Certain trends in research lead one to suspect that the vitamin B series, in whole or in part, may under certain conditions render a disservice to man. This may have a relation to colds and a possible disharmony in the balance of water-soluble versus oil-soluble vitamins. Bacteria, especially the streptococci, seem to need selected vitamins, just as man does. There is much in literature on the subject of the food requirements of bacteria and their use in vitamin assay.

On the virus side of the picture we find that Bloomfield and Lew<sup>11</sup> report that rats on normal diet are normally susceptible to ulcerative cecitis, a virus infection. B-complex-deficient rats were practically immune.

Sprunt<sup>12</sup> found resistance to vaccine virus in undernourished rabbits definitely higher. These and related facts are worthy of attention. At any rate, it is our practice in this field at this time to stop all auxiliary vitamin B supply during a cold, and also during treatment of certain related disorders.

### Summary

- 1. Cod-liver oil concentrate, corresponding to 150,000 units of Vitamin A and 15,000 of D vitamin as an initial dose in twenty-four hours and decreased doses thereafter, has been used in acute colds with the result that in 81 per cent of the cases treated the cold is "cured, abated, or favorably modified."
- 2. No data are here given on the cognate subject of cold prevention and no conclusions related thereto are presented at this time. Nevertheless, many persons have in a manner avoided colds by consistently stopping them in their prodromal stage.

The remedy appears to do no harm. It is recommended for general clinical trial and direct and indirect scientific research. Much of this is under way, especially in the field of direct application of vitamin A and carotene to the affected mucous membrane. The author warns against the interpretation of this report as a presentation of a "cure" for colds and calls attention again to (1) the great diversity of colds, (2) the need of a corresponding intelligent diversity of treatment, and (3) the advisability of the study and recognition of the epidemic nature of colds.

Four things should be considered in the treatment of colds.

This article refers to one, and one only. Any cold treated with this consideration (or any other single consideration) only in mind is improperly treated. It is inevitable that, in spite of what anyone can say or do, persons will proceed to use this vitamin aid in the treatment of colds alone and will neglect other considerations, and will, therefore, upon failure, declare it useless and blame others for their own error or misfortune.

There are at least four considerations in the treatment of any cold:

- 1. The infecting agent—that it be killed or rendered static (local remedies, argyrol, sulfathiazole, are commonly employed and gramicidin is next for trial).
- 2. The mucous membrane—that it be rendered more resistant to infection. It is possible that the present remedy gives aid in this manner.
- 3. The anti-infection agents developed by the body (vaccines are employed to aid this process).
- The body's physiologic processes of digestion, nervous, and circulatory control, etc.

These four factors are like the four legs of a chair. There are other considerations, possibly even more essential. Perhaps more patient, alert search will fully reveal them.

### Case Reports

This report is based upon the cumulative experience of a large number of cases, of various charac-

teristics; while the results range widely in course and outcome, certain patterns are commonly repeated. The following cases will serve as illustrations.

Case 1-Mrs. J. M. had severe winter colds for thirty years. For ten years, her sinuses, especially the left antrum, were regularly infected. Colds would last fourteen to sixteen days. Three years ago she started vaccine and other prophylactic treatment, which moderated the severity of the colds; their duration remained the same; sinus complications decreased, prostration and fever somewhat diminished.

She started routine number 1 in January, 1942, but found it unnecessary to take more than the first one or two doses of 50,000 units of vitamin A and 5,000 of vitamin D. Seasonal vaccine has been continued. The patient takes 50,000 units of vitamin A and 5,000 of vitamin D immediately upon observing the customary lifelong symptoms of oncoming colds. These are stated to be nose irritation, throat irritation, a "headachy," general unpleasant feeling, and the left antrum begins to hurt. These symptoms commonly occur only after a period of overwork or moderate indulgence or both.

The treatment has been successful. There have been no colds for two years. The general condition has improved. Chronic colitis symptoms, previously troublesome, have become quite uncommon, and recur only after marked indiscretions in diet. There has been a marked increase in the patient's margin of work and a marked decrease in restric-

tions of diet and "hygienic" precaution.

Case 2—Miss M. P., aged 48, for ten years has been under general health direction; she reported first in 1932 for colds, headaches, and sinusitis. She suffered regularly from four to six colds during the winter and two severe colds during the sum-

Routine forms of constitutional and local prophylaxis were given-i.e., vaccine, tonics, cod-liver oil concentrate, regulation of diet, intestinal toilet. The colds decreased one-half in incidence and were partly relieved by treatment-i.e., tampons of argyrol, ephedrine, and, more recently, sodium sulfathiazole, 5 per cent solution (aqueous).

In December, 1942, she was given routine number 1. During the winter she had the usual attacks of oncoming colds, but five times she "tossed it off" with one day's treatment. She had the best winter in a decade. Colds appeared to be stopped within twelve hours after the beginning of the treatment. Her success attracted a great deal of attention among the other teachers of the school where she taught, and she developed a large following for this routine of treatment.

The results are reported to be generally excellent except for those who are nauseated by the idea of cod-liver oil. An important fact is that this patient went through "the best winter she ever had" and suffered less from intestinal illness, fatigue, headaches, etc. Some of her associates found it to be noticeable that she was "stronger, younger looking, and more vigorous." This, of course, may be purely incidental, but it does indicate that she suffered no apparent ill effects from this form of treatment.

Case 3—Mrs. H. W. Van S., aged 30, made a rapid recovery from sinusitis. She had been pregnant eight and a half months and was a primipara. She had been under general hygienic and medical care for eighteen years. She suffered from colds of a predominating staphylococcus type, two or three a year, usually mildly infecting the antra and lasting

three weeks, with little prostration. One brother had suffered from chronic sinusitis of the staphylococcus type from childhood to maturity, was sent South every winter until standard direct and indirect prophylaxis and treatment favorably modified the condition and he was able to finish preparatory school and college in the North. A sister suffered from mild, chronic staphylococcus pansinusitis following colds, which was modified by treatment. Another brother had mild colds regularly, with yellow pus.

The patient had been away from routine care for three years. She returned for treatment because she was suffering from severe antrum sinusitis, with a discharge of yellow pus, staphylococcus showing in the urine, a temperature of 103 F., malaise, facial pain, and headache. These symptoms had lasted ten days. The patient expected to be delivered of her first child in seven to ten days.

Her sinuses were treated with standard direct and indirect methods, and routine number 1 was followed. In fifteen hours, her temperature was normal, and her left sinus was slightly cloudy on transillumination and producing no pus. General symptoms abated. Normal delivery followed seven days afterward.

Case 4-Mr. L. F. H., aged 68, was a patient under general hygienic and medical care and observation since his initial health examination nineteen years ago. He had averaged five to six calls a year, until the last three years. Now he reports only at sixmonth intervals. He is vigorous for his age.

He has had no cold for three years. He formerly had two or three severe colds during the winter. They followed a standard pattern closely: one week with fever, two weeks with bronchitis, and one week more to recover. He had two or three colds of less severity during the summer. Colds were mitigated considerably in severity by vaccine treatment and hygienic measures; but he kept on schedule until routine number 1 was prescribed and faithfully followed.

The patient does not take vitamins as a routine but awaits prodromal symptoms. These are a slight sensation of sniffing and a little, indefinite headache. These symptoms, from long experience, he associates with an oncoming cold.

This patient is typical of the group who wait for prodromal symptoms. In this group, some report that, if they fail to start routine number 1 promptly and the colds "take hold," the medication does no good. Others, however, get some result-good, fair, or poor-when it is taken in the course of the cold.

# UDDEN DEATH FROM INFECTION AND NEOPLASM

нео. J. Curpнеч, M.D., Garden City, New York

E purpose of this presentation is to call tention to certain of the less frequent causes lden death encountered in a reasonably ac-Medical Examiner's service in Nassau ty. At the outset it is necessary to explain by sudden death one means death occurring pectedly and in a relatively short time, with presence of either few or no premonitory or symptoms to explain the findings at au-

len Death from Intrathoracic Tumors e first two cases presented here describe inoracic tumors as the cause of sudden death. in itself is relatively rare. The rarity is er increased because of the fact that both e cases occurred in children.

se 1.—J. W. B., a 5-year-old boy, who died on h 30, 1941, first became ill ten days prior to 1 with an attack of acute bronchitis and na associated with fever. Eight days prior ath he developed an erythematous rash on the and abdomen. For the week prior to death ever subsided, but his bronchitis and coughing sted. Occasionally he would have paroxysms sughing associated with dyspnea. On the day ath the child was up and around the house, and ard evening he called his mother and said he was ing. A physician was called, and arrived when shild was in extremis. He died soon after.

he essential finding at autopsy was the presence large mediastinal tumor mass that occupied entire thymic and pericardial region, extending n to the diaphragm below and up to the neck, s to infiltrate the deep cervical structures and thyroid, more especially on the left side The rior limits of the mass were firmly adherent to overlying sternum. The tumor mass consisted a pinkish-white homogeneous tissue which with little resistance, to reveal a pinkish to owish-white cut surface of soft consistency, wing an occasional localized area of greenishow necrotic tissue. Two distinctly cystic is each slightly larger than an English walnut e encountered on the left anterolateral margin he growth. The tumor mass produced distinct eroposterior compression of the walls of the chea and the main bronchi. It is noteworthy t the tracheal, bronchial, and bronchopulmonary uph nodes were readily visualized and were diste and of normal size, showing no relationship with main tumor mass. The pulmonary conus was ind to be completely surrounded by tumor sue. The ascending aorta and its arch were

Read at the Annual Meeting of the Medical Society of State of New York, Buffalo, May 4, 1943. Office of the Medical Examiner, Nassau County

deeply buried in the tumor mass. The junction of the descending aorta and the arch was readily visualized. Section at this point showed well-marked diminution in the lumen of the arch. The spleen weighed 40 Gm. and showed no noteworthy change. The mesenteric lymph nodes were slightly enlarged and had a grossly normal appearance. A large solitary node was encountered in the gastrohepatic omentum and on section had the same gross appearance as the main tumor mass noted in the nediastinum.

The microscopic picture of the tumor was that of a lymphosarcoma of the small-cell type. The lymph node of the porta hepatis was similar in histology. Sections of the bone marrow showed hyperplasia with the presence of many cells, suggesting the morphology of the cells in the tumor. Postmortem blood smears showed no evidence of a peripheral leukemic picture.

Case 2.- A 20-month-old female infant died suddenly on August 15, 1942, while being examined in the office of a pediatrician. The following history was obtained from him. About one week previous to death it was noted that the child had a brassy cough and swollen face. At this time she was taken to her family physician, who elicited the history of a spasmodic cough of about five weeks' duration. At the time of the family physician's examination one week before death, the presence of a slight infraorbital edema was noted. At this examination the temperature was normal. Examination showed the lungs and heart to be essentially normal. The previous history is irrelevant, being that of a normal birth and normal development up to the time of the last illness. During the spring of 1942 it was noted that the child was subject to frequent attacks of infection of the upper respiratory tract. The pediatrician was further able to elicit from the family the fact that during the previous week the child had seemed unable to get her breath and got black in the face. This was worse when she was lying down, and immediately improved when the patient was put in a sitting position. As soon as the child was put on the examining table, she got black in the face and stopped breathing. Sitting up did not relieve her. She was immediately given oxygen, which caused a slight improvement in her condition. Because of the persistent respiratory obstruction, an emergency bronchoscopic examination was done, but no obstructing material was found in the airways; the child died in about five minutes following the final attack.

At autopsy a large intrapericardial tumor mass was found rising from the superior limits of the pericardium. It produced marked distention of the pericardial sac, which contained, in addition about 150 cc. of serosanguineous fluid. The tumor lay superior to the auriculoventricular junction. It showed a yellowish surface mottled with areas of

recent hemorrhage and numerous knoblike projec-The tumor measured approximately 7 by 4 by 4 cm. Its anterior surface was entirely intrapericardial. Its posterior surface extended through the pericardial sac superiorly to a point 1 to 2 cm. above the bifurcation of the trachea, producing a slight amount of compression on the left main bronchus. On section the tumor mass cut with little resistance to reveal a distinctly yellow fatty-appearing cut surface with areas of recent interstitial hemorrhage. It is noteworthy that the tumor mass encircled the pulmonary conus as well as the ascending and transverse portion of the arch of the aorta, the adventitia of which, however, showed no evidence of invasion by tumor. The tumor tissue showed no evidence of invading the auricular structure of the heart. At the junction of the superior vena cava with the left innominate vein, however, an intravascular pear-shaped mass having smooth, yellowish outer surfaces was seen lying directly in the lumen of the vessel, moored to the wall at one point by a rather slender but relatively firm attach-The tumor mass occupied the entire diameter of the lumen. The peribronchial tissue in the region of the hila of both lungs showed infiltration with tumor to the naked eye. The thymus was readily identifiable as a normal and separate mass having no connection with the tumor. other organs showed no noteworthy change.

Histologically, the tumor showed a certain pleomorphism of the cell structure. Sections taken from one area showed a completely undifferentiated collection of cells arranged in alveolar pattern and having large, oval or round, vesicular nuclei with prominent nucleoli, Mitotic activity was evident. There was no evidence of intercellular structure. Other sections taken from other portions of the tumor showed, on the other hand, a definite tendency to the formation of a lining epithelial structure on cords of mature-appearing connective tissue. Many areas showed distinct perithelial or "rosette" formation. The sections from these areas showed associated necrosis and recent interstitial hemorrhage. Other areas of tumor had distinct cleft-like spaces lined by a single layer of cylindrical cells supported on mature connective tissue showing

early hyalinization.

Sections from other areas showed well-marked evidence of interstitial edema. The histologic picture resembles a tumor of nesothelial origin, and in certain areas the features suggest the histologic

pattern of a malignant synovious.

# Comment

Certain salient facts emerge from the study of these two cases. In the first place, it shows the disproportion that frequently exists between the presence of large mediastinal masses and the evidence of respiratory distress.

The first case illustrates the possible relationship between the suddenness of death and the previous history of recent acute respiratory infection, with the likelihood that because of the circulatory changes that might have occurred in

the tumor consequent to an acute infection, increased compression from the tumor might result, which, in turn, might have led to the acute asphyxial death in the course of a paroxysm of coughing. In the second case, the death is probably easier to explain, in that it was very likely the result of a recent hemorrhage into the tumor with associated increased intrapericardial pressure leading to the mechanical effects of tamponade on the heart. The intravascular tumor growth probably played little part in the symptomatology of the case.

### Sudden Death from Infection

In this group are described three cases in which the autopsy findings explain the death in each instance as being due to infection. It is questionable whether the organisms isolated in each instance are the primary invader.

Case 1.—A 39-year-old telephone operator had been sporadically observed by her family physician for several months for gallbladder trouble. The doctor had seen her last two months prior to death. For two weeks prior to death, she had complained of pain in the lower right abdomen, and said she thought she might have a tumor. For two days prior to death, she was unable to work. On the morning of her death, her father came into the house at about 8:30 o'clock, at which time she called to him. He found her sitting on the floor of the bedroom. She said she was too weak to walk. He placed her in a chair and went next door to get his neighbor. Together, they took the patient to the bathroom where she vomited once. She was then put to bed. Her family physician was called, but on arrival found her dead.

The patient was autopsied four hours after The essential findings were in the lungs, heart, and the uterine adnexa. The lower lobe of the right lung showed, on the pleura, a local fibrinopurulent exudate over an area about the size of a silver dollar. The lung tissue immediately beneath the exudate was slightly raised, dark red, and firm. On section through this area, a homogeneous, finely granular surface was seen, the area of involvement extending for less than 1 cm. into the underlying lung structure. The diaphragmatic surface of the lobe showed multiple raised hemorrhagic lobular areas of smaller size. The pleural surface of this lobe showed widespread zones of subpleural hemorrhage. On section the bronchi were free from exudate and showed mild congestion. The larger pulmonary vessels on this side showed the presence of recent antemortem thrombi. The left lung showed well-marked atelectasis of the lower lobe, with moderate congestion of the cut surfaces, there being no areas of consolidation present.

The mitral valve of the heart showed the presence of many small, slightly raised, warty, pinkish-red vegetations which were easily removable from the valve cusps.

The pelvis was the scat of a large lobular, tense, cystic tumor mass about the size of a fetal head, lying slightly to the right of the midline. The uterus was attached to the cystic mass on its anterior surface. The tubes had lost their separate anatomic identity on both sides, each being an intimate part of the cystic mass. External examination of the surfaces showed no gross structures resembling ovaries on either side. The mass was tense and comewhat fluctuant. On section, it evacuated a large amount of thick, greenish-yellow, mucoidappearing material. On washing of the wall, the cavity was seen to be unilocular and to show the presence of multiple, raised, firm, papillary nodules, the largest about the size of a lima bean. Some of these papillary masses had undergone cystic degeneration. The wall itself showed the presence of multiple flattened cyst-like spaces containing hemorrhagic fluid. Careful section throughout the mass failed to reveal any structure identifiable grossly

Culture from one of the involved areas of the lung showed hemolytic streptococci.

Microscopic sections of the lung showed the presence of a recent fibrinopurulent exudate on the pleura. The lung tissue immediately subjacent to this showed marked engorgement of the smaller vessels and the presence of extensive intra-alveolar hemorrhage. Search of the blood vessels in the vicinity of the area of involvement failed to reveal any thrombus formation.

Sections of the ovarian tumor mass showed papillary cystadenocarcinoma of the ovary.

#### Comment

The autopsy findings in this case are rather difficult to evaluate. Unfortunately, no culture of the pelvic tumor mass was made, but from the histologic appearance of the coagulum and the cyst wall, there was no evidence of acute suppurative inflammation. The findings in the lung, by virtue of their localization to one lobe and their multiplicity in that lobe, coupled with the histologic and bacteriologic findings, might suggest an early hemorrhagic pneumonia in which the hemolytic streptococcus is the exciting agent. The presence, however, of recent antemortem thrombi in the pulmonary vessels, along with the absence of intra-alveolar fibrin deposit and cellular exudate, might be taken to suggest unusually early infarction. The valvular changes in the heart are interpreted as a form of indifferent terminal endocarditis, and certainly cannot be adduced as evidence in favor of a Streptococcus haemolyticus bacteremia.

Case 2.—The history and findings of the second case are perhaps more convincing. These deal with a 24-year-old woman, a law student, whose chief complaints were sore throat and hoarseness with dyspnea and dysphagia. The only recent previous illness was a sinus infection in 1937, with no history of colds or sore throats before or since. There is no allergic history either in the family or the patient.

The patient had a slight sore throat twenty-four hours before death, but went to college as usual. On the afternoon of that day she saw a local physi-

cian, who prescribed for the condition. At dinner, the patient complained of the sore throat, but ate normally. She retired early. During the night, the soreness in the throat became more severe, and was associated with profuse draining of mucus from the back of the nose, which she said choked her

She was seen by her family physician the next morning one hour before her death, when she complained of hoarseness, profuse draining of mucus in the back of her throat, with expectoration of a yellowish-white material, inability to swallow, and some difficulty in breathing. On examination by her physician, the patient was sitting up in bed laughing because her voice sounded so strange. At this time, she appeared in no acute distress. Examination of the nose showed a congested edematous left-middle turbinate, with moderate congestion of the right turbinate. Examination of the throat showed a red, dry pharyngeal wall. The heart rate was rapid but regular The lung showed distant breath sounds. Because of her respiratory difficulty, the patient was advised to enter the hospital. While arrangements were being made, the patient suddenly became extremely cyanotic, gasped for breath, and died in less than a minute with a tonic convulsive seizure.

Autopsy was performed four hours after death, The main findings were located in the larynx and trachea, where an acute hemorrhagic laryngotracheitis with edema of the larynx was noted. The lungs showed the presence of edema and congestion with associated intense engorgement of The organs of the neck were rethe bronchi. moved "in toto." There was marked edema present around the fauces. The lymphoid structure at the base of the tongue was distinctly hypertrophic. The epiglottis showed an intensely congested edematous surface. On opening of the larynx, a large amount of frothy blood-tinged fluid was found in the lumen. The mucosal surfaces in the region of the vocal cords were intensely engorged and had a flaming red appearance. In places, the mucosal sheen was lost, so as to give certain areas a dull red, fine, branlike appearance. In addition, many discrete and confluent petechial hemorrhages were seen in the region of the epiglottis, larynx, and upper reaches of the trachea.

Cultures were taken in this case from the larynx, spleen, and the heart's blood. In addition, some of the fresh material was forwarded to Dr. Thomas Francis of the Department of Bacteriology of New York University, who, with Dr. Klosterman's assistance, kindly rendered a report as to the absence of any known filterable virus in the tissues of the larynx. He reported finding, however, a hemolytic Staphylococcus albus as a predominant organism. A similar finding was obtained by us on cultures of the larynx, in which a colon bacillus was also found. Aerobic cultures of the spleen and heart's blood yielded no growth.

Microscopic sections taken from the larynx showed local areas in which the epithelium was edematous and the seat of early ulceration. The underlying subepithelial tissue was edematous and heavily infiltrated with inflammatory cells, the predominant cell being the polymorphonuclear leukocyte.

#### Comment

In summary, then, this is a case of sudden onset of sore throat of slightly less than twenty-four hours' duration, with death due to edema of the glottis associated with the presence of an acute fulminant bacterial infection, caused in all probability by the hemolytic Staph. albus.

Case 3.-A 5-year-old boy, twenty hours prior to his death, was in presumably normal health. At noon of the day preceding his death, he complained that his throat was sore and that it hurt to swallow his food. He had a good lunch, however, After lunch he slept for an hour and a half. Following his nap he went out and played, as a normal child would, until dinnertime. At this time, he complained that he could not eat because his throat was sore. He was given a gargle of aspirin and a dose of milk of magnesia, and sent to bed. Before going to sleep, he appeared in good spirits and played with the other members of the family. His foster mother noted that he slept very soundly until about 3:30 A. M., when he woke her and told her that he had vomited. He went back to bed and appeared quite restless for an hour or two; then he settled down and went to sleep again. At about 6:30 A.M., he awoke and laughed and talked with the son of his foster mother, who was dressing in the room in which the boy slept. At about 7:15, when the child was next seen, he was noted to be having definite difficulty in breathing. At this time, a physician was called. When the latter arrived at about 8 o'clock, the child was markedly dyspneic and, according to the physician, had a pale, ashen color, appearing to be gravely ill. As the physician was about to examine the boy, he stopped breathing, and artificial respiration failed to revive him.

The body was autopsied four hours after death. As in the previous case, the main findings were in the larynx, in which there was marked edema of the epiglottis and laryngeal folds. The gross appearance of the larynx was essentially similar to that in the preceding case, except for the absence of petechial hemorrhages. The lungs showed congestion and edema and the presence on both sides of multiple, slightly raised, sharply demarcated zones of distinctly firmer consistency than the surrounding lung tissue.

Postmortem cultures were taken from the larynx and trachea, the lung parenchyma, the main bronchi, and the spleen. All the organs except the spleen showed hemophilus influenzae; the culture of the spleen was sterile. In addition, green streptococci were obtained from the larynx and trachea and lung.

Microscopic sections of the lung in this case showed a histologic picture quite similar to that seen in the first case, in which the air spaces contain abundant red cells. There was also evidence of widespread interstitial edema. In addition, the regional bronchioles showed a purulent exudate, and in one or two fields the air sacs were seen to contain a moderate distribution of polymorphonuclear leukocytes among the red cells.

#### Comment

In summary, the cause of death in this case is edema of the glottis, consequent to an acute laryngotracheitis caused in all probability by the hemophilus influenzae. This case in some respects calls to mind the recent report in the J.A.M.A. by Sinclair, \* who describes a form of acute laryngitis caused by hemophilus influenzae, type B, and associated with bacteremia. He reported 10 cases, all of which showed bacteremia and none of which showed hemolytic streptococcus in the nose or throat. In two of the fatal cases that were autopsied, the organism was recovered from the lung without any gross or microscopic evidence of pneumonia. The symptoms and signs of his cases were severe sore throat, laryngitis, fever, leukocytosis, and signs of shock; the children were markedly toxemic. In his observed cases, the laryngitis was associated with edema and congestion of the epiglottis and larynx. It is noteworthy that the dyspnea caused by these anatomic changes was not relieved even by tracheotomy. The severity of onset and the fulminant nature of the course of this disease process are evident from the fact that one patient died three hours after onset of the symptoms. It is noteworthy that this is essentially a disease of childhood, as none of his patients was older than 7 years, the youngest being 41/2 months old. The similarity between Sinclair's group and our case lies in the recovery of the influenzal organism, the type of which is undetermined because of the lack of facilities in our laboratory. The dissimilar feature is the absence of bacteremia in our case, this inference being drawn from the negative culture of the spleen.

#### Conclusion

From the presentation of the evidence, no attempt has been made to explain the mechanics of sudden death in the individual case. It is evident from the case reports that mechanical asphyxia was a predominant factor in one case. In the case of the child showing presence of hemophilus influenzae, the absence of any mechanical obstruction to the airways, coupled with the presence of the organism and previous knowledge of this disease in children, lends support to the supposition that death is due to a rapidly acting toxemia. In the case of the malignant mesothelial tumor, it is likely that the suddeness of the death can be explained on the basis of

<sup>\*</sup> Sinclair, S. E.: J.A.M.A. 17: 170-173 (July 19) 1941

recent hemorrhage into the tumor, causing a tamponade of the heart, although the latter evidence is none too secure. The predominant char-

acteristic of the group of cases is the total disparity between the autopsy findings and the antecedent evidence of disease.

#### A.M.A. URGED GROWING CINCHONA IN U.S. YEARS AGO

"In 1738, a hundred years after the introduction of the Peruvian bark into our pharmacopeia, La Condamine had already foreseen the exhaustion of the South American supply as a consequence of the purely destructive methods of 'production' in New Granada, Ecuador, Peru, and Bolivia. After a hundred years had passed the situation had grown so dangerous indeed that the Dutch and the English started cultivating the cinchona tree in their own colonies, the former in 1854 in Java, the latter in 1860 in the Neilgherry Hills of southern

"The 'Transactions' of the fifteenth annual session of the American Medical Association, held in 1864 in the City of New York, contain a little memorandum of Dr. D. J. Macgowan (apparently an Army surgeon) of Washington, D.C., on the 'Naturalization of Cinchona on the Eastern Continent.' Macgowan dealt with the Dutch and English experiments and recommended that they also be tried in Haiti. The assembly reacted favorably to the suggestion, and on the motion of Dr. J. H. Griscom, the famous New Yorker Quaker and sanitarian, appointed a committee composed of three of its most distinguished members... to confer with the Haitian minister on the subject.

"Three years later, in 1867, the Medical Society of Wayne County, Michigan, submitted to the eighteenth annual session of the American Medical Association a paper by its member, Dr. J. M. Bigelow, which examined the whole cinchona situation in more detail and boldly and rightly asked the introduction and cultivation of the cinchona tree in the United States. Dr. Bigelow designated western Texas, Arizona, or Lower California as best fitted for such plantations..."

A committee was appointed to "memorialize" Congress on this vital question and the next year, 1868, a report of the committee was read in the Association's Section on Chemistry and Materia Medica. A new committee was appointed and for seven years this committee, under the leadership of Dr. L. J. Deal, of Pennsylvania, carried on a vigorous, intelligent fight for the cultivation of the cinchona tree in the United States.

"At the twenty-first annual session, in 1870," Dr. Ackerknecht continues, "Dr. L. J. Deal submitted a report of the committee, consisting mainly

of a proposed memorial to Congress. . . . It starts with an explanation of the medical value of quinine and then gives some interesting data on the economic implications of the problem: For example from 1859 to 1865, \$2,287,250 worth of bark and quinine salts were imported into the United States; between 1861 and 1865 the United States Army purchased 1,198,000 ounces of quinine (the average annual consumption of the United States before World War II was 5,000,000 ounces). The memorial describes the danger arising from the exhaustion of the Peruvian supply and recommends the cultivation of cinchona in California, which seemed to be even better suited for such an enterprise than India. The aid of the California State Board of Agriculture and the Sacramento Medical Society had already been secured. The memorial concludes:

The American Medical Association therefore asks, in view of the foregoing facts, that the Congress of the United States would appoint a commission of scientific men for the following purpose:

purpose:

1. To determine what portion if, any, of the public domain of the United States will produce the cinchona, and which may be set apart for this purpose.

2. To determine what species may be best transplanted

and will furnish the greatest amount of active principles.

3. That they be authorized to visit such South American countries as they may deem necessary in order to determine these points, employ a competent botanist to assist them, and that our consuls in such States be instructed to further these

investigations.

4. That they be empowered to negotiate for, and obtain a proper quantity of seeds and plants.

"In 1872 Dr. L. J. Deal reported 'a gratifying progress, Congress having been memorialized with a favorable prospect of success.' A second memorial to Congress was submitted. The 'Transactions' of 1874 contain a more detailed report of the committee, which still sounds rather optimistic: Since 1868 'three memorials had been presented to Congress. . . . ' The committee had obtained the support of the Botanical Gardens in Washington, D.C., of the Department of Agriculture and of the Horticultural Society. President Grant, in his message relating to the purchase of San Domingo, had advanced the argument that the climate and the soil of this island were suitable for the cultivation of cinchona. The committee was continued.

"But, alas, at the twenty-sixth annual session in 1875, after a 'report of progress,' the committee was discontinued. We do not know the exact reasons and motivations for this step but, though regretable, it is only human that after seven years of incessant endeavor the Association grew tired of preaching to deaf ears and did not, like Jacob, go on for another seven years of bondage. In this action, which seemed only an episode but has now become so consequential, the American Medical Association showed a considerable degree of informedness and of foresight in the public interest. Like so many plans of prevention, its plan probably suffered from looking more costly than expedient. The failure seems no reason to give up in similar situations in which our scientific conscience commands unpopular proposals in the public interest. On the contrary, it seems to be rather an admonition to be still more perseverant."

filtrated with inflammatory cells, the predominant cell being the polymorphonuclear leukocyte.

#### A.M.A. URGED GROWING CINCHONA IN U.S. YEARS AGO

We would not be confronted today with a quinine shortage had the advice of the American Medical Association seventy-five years ago to grow our own cinchona trees been heeded, Erwin H. Ackerknecht, M.D., Baltimore, points out in the Journal of the American Medical Association for October 9. "It is now common knowledge," Dr. Ackerknecht

writes, "that the Japanese, in taking Java, cut off the source of almost the entire prewar quinine supply of the world. It is equally well known that the resulting quinine shortage is still, in spite of many ingenious and valuable countermeasures, one of the most serious problems of medical warfare. The American Medical Association can be rightly proud of having been, seventy-five years ago, the pro-tagonist of a plan which, if it had been executed, would have saved us our present difficulties.

"In 1738, a hundred years after the introduction of the Peruvian bark into our pharmacopeia, La Condamine had already foreseen the exhaustion of the South American supply as a consequence of the purely destructive methods of 'production' in New Granada, Ecuador, Peru, and Bolivia. After a hundred years had passed the situation had grown so dangerous indeed that the Dutch and the English started cultivating the cinchona tree in their own colonies, the former in 1854 in Java, the latter in 1860 in the Neilgherry Hills of southern India.

"The 'Transactions' of the fifteenth annual session of the American Medical Association, held in 1864 in the City of New York, contain a little memorandum of Dr. D. J. Macgowan (apparently an Army sur-geon) of Washington, D.C., on the Naturalization of Cinchona on the Eastern Continent.' Macgowan dealt with the Dutch and English experiments and recommended that they also be tried in Haiti. The assembly reacted favorably to the suggestion, and on the motion of Dr. J. H. Griscom. the famous New Yorker Quaker and sanitarian, arranged to committee composed of three of its Haitian minister on the subject.

"Three years later, in 1867, the Medical Society of Wayne County, Michigan, submitted to the eighteenth annual session of the American Medical Association a paper by its member, Dr. J. M. Bigelow, which examined the whole cinchona situation in more detail and boldly and rightly asked the introduction and cultivation of the cinchona tree in the United States. Dr. Bigelow designated weeks. western Texas, Arizona, or Lower California as best fitted for such plantations. . . . "

A committee was appointed to "memorialize" Congress on this vital question and the next year, 1868, a report of the committee was read in the Association's Section on Chemistry and Materia Medica. A new committee was appointed and for seven years this committee, under the leadership of Dr. L. J. On the contrary, it seems to be rather an admonition to be still more perseverant.'

### THE INCIDENCE OF DEFICIENCY SYNDROMES

HERBERT T. KELLY, M.D., and MYRTLE SHEPPARD, A.B., Philadelphia

In THE words of McLester: "True, deficiency disease occasionally appears in an outspoken form, as in scurvy or beriberi, but with vastly greater frequency it takes the form of vague borderline states of ill health, states which destroy the patient's happiness and impair his usefulness. These subclinical forms are manifold in nature...."

This study was undertaken to indicate the prevalence of recognizable early forms of deficiency disease, which, according to Aring and Spies,<sup>2</sup> is difficult to measure quantitatively, but which can be substantiated by clinical and laboratory findings.

Material. The same 225 patients, who were under our medical supervision and represented a cross section of individuals from the upper income levels, were used for this study as for our previous study on dietary deficiencies.<sup>3</sup>

Method: For each of the 225 patients, we had a medical and dietary history (as discussed in our previous paper), and record of medical and nutritional examination. In addition, indicated laboratory tests and x-ray studies were conducted. In conjunction with the regular medical examination, the nutritional examination considered: general appearance and condition of the skin and its appendages, the eyes, the lips and oral contents, and the extremities.

The laboratory procedures consisted of biophotometer reading, hematologic studies, sedimentation reaction, serologic and blood chemistry tests, urinalysis, basal metabolism measurement, gastric analysis, diagnostic gallbladder drainage, examination of feces, electrocardiography, Althausen galactose test for intestinal absorption, glucose tolerance test, and plasma prothrombin determination. Also included among the laboratory procedures were diagnostic tests for specific vitamin and mineral deficiencies, such as the ascorbic acid tolerance test, a blood calcium and phosphorus determination, a blood test for total iron, and a twenty-four-hour analysis for calcium and phosphorus in the urine. X-ray studies included roentgenology of the bones, joints, teeth, heart, lungs, and gastrointestinal tract.

#### Recognized Deficiency Signs

From the findings of the medical and nutritional histories, physical and nutritional examinations, laboratory tests and x-ray studies, we tabulated the data recorded in Table 1. The signs

This study was made possible by a grant from White Laboratories, Inc., Newark, New Jersey.

and symptoms listed are usually associated wit deficiency states and are a compilation of re search findings, using as a model the table, "Gros Evidences of Malnutrition," compiled by Jolliffe McLester, and Sherman.<sup>4</sup>

#### Dextrose Tolerance Curve

"Malnutrition," according to Robinson, She ton, and Smith, 23 "disturbs the dextrose toler ance of a patient and produces a clinical condition which might be called pseudodiabetes." Accordingly, we listed in Table 1, under "Ce Oxidation," a diabetic-like dextrose toleranc curve as one of the probable signs of malnutration. However, according to our data, only three patients exhibited a dextrose toleranc curve similar to that described by Robinson et all.

On the other hand, our observations lead us to believe that hypoglycemia and malnutrition are closely interrelated—how closely can be determined only by more thorough investigations. In our limited survey, many of the patients who exhibited clear-cut deficiency syndromes showed, or laboratory test, indications of hypoglycemiathat is, after the oral administration of 100 Gm of dextrose, the patients complained of the usual manifestations of dizziness, faintness, and the like.

Many of the syndromes listed in Table 1 an "specific" for more than one suggested vitamin or mineral deficiency, indicating the interrelation ship among the dietary essentials. In addition to the signs and symptoms listed, such condition as abnormal weight, abnormal height, pallor and fatigue may also be indices of general mal nutrition.

#### Intestinal Signs of Deficiency

Deficiency states are "mirrored rapidly" in abnormal changes in the eyes, skin, and mucous membrane; in the skeletal, cardiovascular, urinary, and gastrointestinal systems; and in aberrations of cellular oxidation. Many authorities in roentgenology are of the opinion that rarely does a nutritional deficiency exist without associated alterations in the roentgenologic appearance of the gastrointestinal tract. 24,25

The intestinal pattern of impaired nutrition, as visualized roentgenologically, consists of two stages. In the mild or primary stage the pattern is one of hyperirritability and hypertonicity with numerous contraction waves—a picture of general intestinal unrest. In the secondary stage of the abnormal pattern the intestinal picture is one

des which are not continuous; invasion of cornea by capnounced in superficial layers of conjunctivae. 115 patients), 943 teeth had been extracted and 804 were

of sluggishness and irregular peristalsis. Thus, the primary stage represents functional changes, the secondary stage morphologic alterations. The morphologic change of the gastrointestinal

tract is revealed, by x-ray, as an alteration in the mucosal pattern of the small bowel, especially in its upper loops.<sup>26</sup> The variation of intestinal change from a state of unrest to a state of slug-

gishness is comparable to the change that takes place in the deep tendon reflexes in a thiamin deficiency. In the mild deficiency state the knee jerks are overactive; in the advanced stage of thiamin deficiency there is an absence of knee jerks.

#### Nutritional Inadequacy

Recognizing and interpreting the symptoms and signs of nutritional deficiency are only half of the diagnostic problem. The other half of the problem is to discover the cause of the deficiency. It is a simple matter to obtain and analyze the diet in order to determine the possibility of a "dietary inadequacy"—failure to ingest an essential nutritional factor or factors in amounts sufficient to meet the existing requirements of the body. However, it has been found that inadequate dietary supply of a nutritional factor is only one of the causes of "nutritional failure."

In addition, certain mechanical, chemical, and psychogenic conditions may interfere with assimilation of nutritional factors and deficiency may result not only because of dietary inadequacy but also because of nutritional inadequacy due to the patient's failure to digest, absorb, fabricate, and store the essential nutrients in the liver, distribute and utilize the products of digestion, or to loss of formed elements. It is important, in addition to prescribing therapy, to attempt to correct these mechanical, chemical, and psychogenic conditions. For example, the causative factor of a syndrome of perlèche associated with a smooth, burning tongue and resembling ariboflavinosis,7 is often a mechanical defect such as ill-fitting or inferior dentures or an absence of dentures and not inadequate riboflavin intake.

In nutritional inadequacy, because of faulty assimilation of the nutritional factor or factors, the demand for these is thereby increased. If the supply of these factors is not increased, nutritional failure or deficiency disease may result. Table 2 lists the somatic conditions which may bring about nutritional inadequacy, and the prevalence of these conditions among the 225 patients studied.

In addition to the somatic conditions recorded, others such as nausea, food allergy, migraine, mental disorders (neurasthenia, neurosis, psychoneurosis, and psychosis), and major surgical operations interfere with the normal food intake. Normal conditions such as lactation, pregnancy, growth, etc.—all of which increase nutritional requirements—have not been considered in this comparative study. A comparison of Tables 1 and 2 reveals the fact that conditions such as histamine achlorhydria, alterations in the gastrointestinal pattern, and polyuria may be not only

the results but also the causes of nutritional fail-

When confronted with possible nutritional deficiency disease the physician should attempt to determine whether the patient's symptoms and signs are due to dietary inadequacy or nutritional inadequacy.

Certain dietary conditions also may bring about impaired digestion, absorption, etc. For example, a low fat intake interferes with the absorption of vitamin A, excessive fat has an inhibitory effect on riboflavin; the combination of mineral oil and carotene, or vitamin A and iron, or of phosphorus and iron are each incompatible, for they form insoluble compounds that are not utilized by the body, but instead are passed out in the form of waste material—each bringing about possible nutritional failure.

# Correlation of Diet with Signs and Symptoms of Deficiency

After accumulating all our data we attempted to compare the dietary findings with the clinical information provided by the patients' histories, physical and nutritional examinations, and laboratory tests. Chart I compares the incidence of dietary deficiencies with that of the specific signs and symptoms which we observed.

In stating that 42 per cent of our patients had a vitamin A deficiency and 85 per cent a thiamin deficiency, we wish to emphasize that we may not be completely accurate, for these conclusions are merely assumptions. Such statements could be entirely accurate only if we had conducted upproved quantitative tests to determine the concentrations of the more important vitamins and minerals in the blood stream or other body fluids. Such tests were conducted for calcium, phosphorus, iron, and vitamin C. Unfortunately, however, these tests were not done on all the patient; studied. Therefore, when our data were accumulated we concluded that a patient had a specific nutritional deficiency when he exhibited one or more manifestations of that deficiency, which is of course limited in its scientific merit.

We found that all the patients who had a dietary deficiency of a specific nutritional factor, with the exception of protein and iron, also seemed to exhibit the characteristic syndrome of this specific nutritional deficiency.

In the cases of protein and iron, the dietary deficiency seemed more prevalent than the specific deficiency syndromes, apparently because edema, impaired wound healing, and microcytic anemia are the only specific signs of protein deficiency which have been listed in our tabulations, and anemia and subnormal iron content of blood are the only specific signs of iron deficiency which are listed. The other signs and symptoms of these deficiency states are not too well defined and include such general manifestations as fatigue, underweight, irritability, and the like-all of which may be due to deficiency of other nutritional factors as well and, therefore, cannot be considered in the numerical count of the symptomatology in our patients exhibiting deficiencies of protein or of iron.

Interestingly, more patients seemed to exhibit syndromes of deficiencies of vitamin A, thiamin, riboflavin, vitamin C, and calcium than their diets indicated. We attribute the possible higher incidence of these deficiency syndromes to the large percentage of patients who had conditions that interfered with their adequate food intake.

In most instances, a patient seemed to exhibit more than one specific deficiency syndrome, thiamin and riboflavin deficiency syndromes usually occurring together. We did not extend this comparison to vitamins and minerals other than those included in Chart I, since our dietary information was inadequate. However, it is of interest to point out that approximately 35 per cent of the patients seemed to manifest one or more signs of nicotinic acid deficiency syndrome. Again, we did not consider caloric supply in this comparative study, since, in our opinion, the caloric daily requirement is flexible and not so important as the requirements for other dietary Also, we have found that most essentials. women of moderate activity do not require 2,500 calories daily and most men of similar activity do not require 3,000 calories daily, as specified in the "Recommended Daily Allowances."28

#### Summary and Conclusions

In this study of 225 patients from the upper income levels the indicated prevalence of deficiency syndromes was studied. Complete medical and dietary histories were secured and thorough physical and nutritional examinations, indicated laboratory tests, and roentgenologic studies were conducted to determine the cause of the deficiency. The causes of nutritional failure are dietary inadequacy and/or nutritional inadequacy. The physician should be thoroughly familiar with the signs and symptoms of nutritional failure, and have a thorough understanding of the somatic and psychogenic factors that interfere with mechanical and chemical digestion, with absorption of the products of digestion, with conversion and storage in the liver, with distribution, with the degree of utilization, and with the loss of formed elements, since these factors bring about nutritional failure in spite of dietary adequacy. Changes in the intestinal pattern should be of vital importance to the clinician and offer a clue as to the stage of the deficiency.

#### MIDDLE CLASS AMERICA

To attempt a practical application of tax policy and government spending to the middle class American, let us consider the American medical profession as a part of our economy.

We all know that the emergency of illness is one of the worst hazards of the family of average means. Proposals for government-supported medical services can therefore be dressed most effectively

"in the language of the true humanitarian." It is not difficult for any of us, now that the Treasury Department has recommended an increase of twelve billion dollars in the tax load, to imagine an income tax for the average American family which might make payments for private medical service impossible.

There is now pending in Congress a proposal for the government to spend more than three billion dollars on medical and hospitalization service.

That three billion dollars is a quarter of the tax increase sought by the administration. So with the one hand the government would take away from the middle class American his ability to provide private medical care for himself and his family, and with the other it would offer him government hospitalization and medical care.

Physicians in private practice would find their incomes from private sources at the vanishing point. They would have to seek government employment. Thus, in this vital matter of hospitalization and medical care, the individual American, as well as the professional man, would be thrown on the mercy of the government or put in the clutches of the government, however you want to look at it. Think of the blow to American individualism that this one element of the problem threatens!—Providence Journal, August 5, 1948

# CONTRIBUTION OF MODERN PSYCHIATRY TO THE PHYSICIAN AND SURGEON

SMILEY BLANTON, M.D., Nashville, Tennessee

MODERN psychiatry has, I think, important contributions to make to the physician and surgeon. There are certain primitive impulses of love and hate in the unconscious mind of every human being which have a decisive influence on health and disease, on life and death. The development of these impulses can be understood by reviewing, briefly, the development of the child.

The human infant remains in a state of dependency on its parents, especially its mother, for three or four years. This relationship of the child to the mother is most intimate. The child is fed from the mother's body, cleansed by her, and its eliminative functions are cared for by her. It must be loved and petted also, if it is to be a healthy, normal child. All infants desire to retain this childish, intimate, bodily relationship to the parent, and the fundamental conflict in the life of every human being is incurred in the act of breaking away from this infantile relationship and developing more adult attitudes. Every child is rejected, in a certain sense, by his parents, because it is obvious that no person can act toward his mother at twenty as he would as a baby of two. But every time the child is frustrated in his desire to remain an infant with his parents, he becomes angry and has feelings of hatred toward the parent. It is common enough to hear a child say to his mother, who has refused him something, "Go away! Go away! I hate you. I wish you were dead."

The child, of course, loves his parents at the same time that he has these feelings of antagonism due to his frustration. But if the child is loved too much, or if he is not loved enough (one must apply common sense rules as to what is too much or too little), there develops in him a morbid amount of aggression and antagonism. Normally this aggression and antagonism is overcome by, or neutralized by, love, and no harm results.

Whenever the aggressive feelings are morbidly strong, they are repressed into the unconscious mind, and it is in the unconscious mind that there develop the impulses that give rise to morbid physical and mental conditions. Most of our behavior, and the attitudes that make for health or sickness, spring from the unconscious mind. This is one of the cornerstones of psychological medicine.

Perhaps a few examples will illustrate.

The first is a young woman, 34 years of age. She is the second of three girls; her older and younger sisters are very good-looking, attractive, and vivacious. This woman, as a child, was plain, quiet. and rather subdued. As she grew up, and as her sisters became more and more popular with boys, she developed more and more the feeling of being the "ugly duckling" of the family, and that no boy could care anything for her. In her unconscious mind there developed a marked feeling of aggression toward her sisters, which she reacted against by becoming very subservient to them and serving them in every way she could. She washed their clothes, she put up their luncheons, she did their typing for them, and made herself a veritable door But as a compensation for her position of inferiority, she became a brilliant student, graduated with honors from high school and college, and, after teaching for a time, got the degrees of Master of Arts and Doctor of Philosophy. She had no play life and she had no love life in the sense that she had no beaux, nor friends of the opposite sex, or really even any close women friends.

At about the age of 30 she developed symptoms of extreme fatigue. This was due to the fact that she had no emotional outlet. After a time, she developed mucous colitis. It was thought that her appendix might be the cause and it was removed, but with no benefit. Later on, because of a rather marked anemia, due to her listlessness, lack of exercise, and poor eating, her frontal and maxillary sinuses were operated upon because it was thought that they were the "guilty parties." Later on she had six teeth drawn and, sometime later, because her menses were prolonged, she had a curettement.

But all of this surgical procedure did nothing to relieve her fatigue. Indeed, it grew so pronounced that she was a semi-invalid and had to arrange to do half-time work in her school. It was only when the unconscious basis of her conflict was resolved that she was able to overcome her fatigue and lead a normal life.

Another case was that of a young woman who was very much attached to her mother and father. She was the youngest of six children and the parents, feeling that she was the last child, kept her a baby, psychologically, long after the time when she should have grown up. In order to escape this entangling family situation, and to avoid the bitter quarrels she had with her parents, she married at seventeen. She was psychologically unprepared for marriage, but within two months she became pregnant and subsequently had a child. This was quite a strain upon her because she was not ready for motherhood, and was quite badly torn at the birth of her child. About three years later, at the insistence of her husband, she became pregnant again. This time

Associate professor of clinical psychiatry, Vanderbilt University School of Medicine, Nashville, Tennessee.

occurring together. We did not extend this comparison to vitamins and minerals other than those included in Chart I, since our dietary information was inadequate. However, it is of interest to point out that approximately 35 per cent of the patients seemed to manifest one or more signs of nicotinic acid deficiency syndrome. Again, we did not consider caloric supply in this comparative study, since, in our opinion, the caloric daily requirement is flexible and not so important as the requirements for other dietary essentials. Also, we have found that most women of moderate activity do not require 2,500 calories daily and most men of similar activity do not require 3,000 calories daily, as specified in the "Recommended Daily Allowances."28

#### Summary and Conclusions

In this study of 225 patients from the upper income levels the indicated prevalence of deficiency syndromes was studied. Complete medical and dietary histories were secured and thorough physical and nutritional examinations, indicated laboratory tests, and roentgenologic studies were conducted to determine the cause of the deficiency. The causes of nutritional failure are dietary inadequacy and/or nutritional inadequacy. The physician should be thoroughly familiar with the signs and symptoms of nutritional failure, and have a thorough understanding of the somatic and psychogenic factors that interfere with mechanical and chemical digestion, with absorption of the products of digestion, with conversion and storage in the liver, with distribution, with the degree of utilization, and with the loss of formed elements, since these factors bring about nutritional failure in spite of dietary adequacy. Changes in the intestinal pattern should be of vital importance to the clinician and offer a clue as to the stage of the deficiency.

179

surgery and medicine is the insistence on looking at the patient as a total organism that reacts on various levels: psychological, physiological, anatomical, etc. Instead of speaking of "organic" and "functional," psychological medicine would say that every illness, whether mental or physical, is based on three things:

- 1. The organism which the patient inherited.
- 2. The childish patterns, which are deep in the unconscious mind and which remain throughout life.
- 3. The present situation.

The old concept of organic and functional disease is no longer adequate, because it implies that the patient's body and mind are in separate compartments—that is, that the psychologic, the physiologic, and the anatomic sides of man are separate entities. This is not the case. Everything a person suffers from is organic in the sense that it is caused by changes in the body. Therefore, it is not a case of whether it is organic or functional, but whether the organic changes in the body are reversible or not.

For example, we saw a man not long ago who had to work in a very noisy place over switch engines that were clanging and banging all day long. He was also worried about his child, who has had infantile paralysis and was left with a lame leg. This man developed toxic goiter. It is very obvious that such a case can be called neither organic nor functional. Perhaps his thyroid was the weakest spot in his organism, but it seemed very obvious that the strain of noise and the worry over his child were the main factors of his disease. Rest, medical treatment,

arrangements for adequate treatment for his child, and the changing of his working place so that he would avoid the noise, brought about a cure.

' The last, and probably one of the most fundamental contributions that psychiatry has to make, is that it rightly has to do with the average, normal person, both in health and in sickness. The conflicts that exist in the average child as he grows up, may, as we have said, give rise to physical illness, neuroses, or psychoses. And psychologic medicine emphasizes that when a person is sick he is not merely a "case" of pneumonia, or of gallstone, or of appendicitis; he is a human being who has some pathologic condition of his body, but whose thoughts, feelings, attitudes, philosophy, and religious outlook play a vital part in his recovery. It also emphasizes the fact that in any illness he regresses to some extent, to a childish level, and that in a really serious illness, one in which the very life has been threatened, it requires a definite retraining of the patient's thoughts, feelings, and will in order that his adult attitude may be regained, else we see him fail to make an adequate convalescence and remain semi-invalid if he recovers.

Finally, dealing with the more serious mental conditions, the neuroses and psychoses: except for that 20 per cent which is caused by organic injury of the brain, we find their cause in these very regressions back to an infantile level, in these childish patterns and attitudes which are always present in the unconscious mind and which are always ready and waiting to come out under, to them, favorable circumstances, which are, indeed, imperishable.

#### THE HUMAN SIDE OF MEDICINE

Sir—Without in any way questioning Dr. Stark Murray's sincerity (Nov. 6, p. 591), one must wonder how he conceivably arrives at the belief that "the change over from an individualistic system of medicine to a comprehensive national service will give us the opportunity to humanize completely the relationship between patient and doctor. . . ." One indeed questions what humane treatment means to Dr. Murray. Others beside myself no doubt saw State medicine in action in Socialist Vienna—magnificent hospitals magnificently equipped, where the patient was just "Case No. 793," and often treated in a way that would never (up to now) be

tolerated anywhere in this country. This was not because the doctors and surgeons of that famous medical centre (in pre-Nazi days) were any less humane than their counterparts in London, but because the relationship between patient and doctor had been brought down to the level of that between the taxpayer and the income-tax inspector—not a person but a thing, not a personality but a body. Does Dr. Murray seriously consider that his relationship to an individual in his "official capacity" is ever more human than to that individual as an individual?—I am, etc.—Alan Maberly (in British M. J.)

# THIRD REGISTRATION OF NURSES TO BE HELD FEBRUARY 7 TO 12

Every graduate nurse in the United States is asked by the War Manpower Commission to go to her local hospital or health agency during the week of February 7 to 12 to register. Nurses of all ages, no matter how long it has been since they

engaged in active practice, are asked to register at this time.

The 25,000 members of the women's auxiliary of the American Medical Association have volunteered to assist the hospitals in the registration. she suffered from pathologic nausea. After three months of pregnancy, she had a spontaneous miscarriage. Soon after this, she began to suffer from severe headaches, attacks of tachycardia, and of dyspnea. She was treated for about a year without very much result.

It is my experience that pathologic nausea in pregnancy may often be due to an unconscious rejection of the child. Psychoanalysis showed that the patient bitterly resented this pregnancy—that she had wanted to be rid of the child, and that she was considered by her unconscious mind (which considers wishes as acts), as having caused the abortion herself. Of course, she was entirely unconscious of this mechanism, but it is proved over and over again that there can be severe physical symptoms caused by unconscious wishes of which the conscious mind is entirely unaware.

I may say in passing that every induced abortion, no matter how cool-headedly it is planned, is likely to give rise to physical symptoms, because whatever may have been the conscious decision in the matter, the unconscious mind accuses the individual of murder. In every such case, it is our experience that where there are physical symptoms, there should be an investigation of the deeper attitudes of the patient.

Not only is this true in induced abortions, but even in spontaneous miscarriages. There often occur serious psychologic symptoms when miscarriage occurs, because the unconscious mind accuses the woman of the sinful act of murder, since one side, at least, of a woman's mind often resents the existence of pregnancy.

The third case is that of a young man who was on his way to a neighboring town to ask a girl, with whom he had broken his engagement of marriage, to renew the engagement. He was doing this under the influence of his family's persuasion. He did not really love the girl and did not really want to marry her. On the way to the town, driving his car at only fair speed, he came to a curve in the road, but instead of taking the curve—he does not know whyhe drove straight forward into a tree and was thrown against the windshield, breaking his jaw and his arm. By the time he had got well, he had given up the idea of marrying the young woman he had been going to see. Since the man was intelligent, a skillful driver, and had not been drinking, it seems obvious that the accident was caused by some unconscious motive. We were later able to prove this in a psychoanalysis. The accident was a purposive accident, from the standpoint of the unconscious mind, of course, in order to avoid the marriage.

It has been our experience that whenever a person has an accident with which he has anything to do, every circumstance should be analyzed to see if the accident was not an unconscious and purposive one. Undoubtedly many accidents are caused by the unconscious desire to

have them. This may seem strange, but it seems also to be a fact.

The next is a group of cases of appendicitis. We studied three for comparison, two of them in young men and one in a girl of 17. All of them had pain, rigidity, and tenderness over the appendix area. The men had very slight leukocytosis; none of them had fever. The two young men had inflamed, congested appendices. The young woman's appendix was entirely normal.

There was nothing in the history of the men to indicate emotional conflict but in the girl there was a serious emotional difficulty, since, a short while before, her father had deserted her mother. Even more important, she was quite fat and felt herself to be very unattractive. The family was without resources and she had to start to work. On the way home from being given a physical examination for a job, she developed symptoms of appendicitis. It was a clear case of hysteria simulating appendicitis.

The question arises: what should be the attitude of the surgeon in such a case? Should be or should he not postpone the operation? In such cases, it has been the experience of individual surgeons, as well as psychiatrists, that it is best to tell the patient that there is no proof that he has appendicitis, but that the surgeon is going to operate to see what the condition is, because he considers it unwise to take a chance; then, if no pathology is found, the patient should be told that the condition was an emotional condition and some effort should be made to help him overcome it. Otherwise, he may very likely develop some other physical symptoms simulating another pathology, causing another operation to be performed.

Let me give one more example of the influence of the unconscious impulses of love and hate on life and death. A woman 47 years old came into a hospital because of severe attacks of gallstones. She had been in the hospital for about a week, being prepared for the operation, when a letter from the mistress of her husband fell into her hands. She and her husband had seemed very close to one another, and she had no idea that he was untrue to her. She did not tell her surgeon about this.

She took the ether rather badly and remained in shock for some time after the operation. She seemed The surgeon could not undervery depressed. stand why she should have reacted so badly, and feeling that something was disturbing her, asked her what was on her mind. She told him, and she told him also that she did not care to live and did not intend to. Five days after the operation she went into a coma and a week later she died.

It seems to be a fact that whether patients ... live or die depends to a large extent on their will to live, and their will to live depends on whether they feel themselves loved, wanted, needed. One contribution of modern psychiatry to

#### The Advance of New Methods

The reason for this deplorable state of affairs is that the tuberculosis specialist cannot support himself in a small community. He is forced to engage in general practice. His hospital connections are frequently jeopardized by the nature of his work. His interest in tuberculosis fails and finally dies. His pneumothorax instrument rusts on its hinges. But, just as the cottage sanatorium has fallen into disrepute, so has the tuberculosis specialist been completely outdistanced by the march of events. New technics and methods have come into common use, all of which are essential for the diagnosis and treatment of diseases of the chest. They include physical diagnosis, radiography, bronchography, pneumothorax, thoracoscopy, bronchoscopy, esophagoscopy, and surgery. They cover different aspects of a common field of knowledge and endeavor. A practitioner familiar with these methods is not simply a tuberculosis specalist; he is a pneumonologist, capable of rendering expert service on any of the minor or major procedures connected with the diagnosis and treatment of thoracic disease. His activities do not interfere with those of the general practitioner, who, on the contrary, should extend his sphere to include the care of uncomplicated pneumothorax cases. Hence, such a specialist would find his usefulness in a small community or on the staff of the average general hospital equal to that of any other specialist and his financial position equally secure.

#### Obstructionism in the Field

The realignment of medical and allied services according to the above plan would make four

contributions of inestimable value to the antituberculosis fight. It would (1) extend the field of expert service in lung diseases, including tuberculosis, to all the people, immediately; (2) bring the general hospital, with its intimate public contacts, back into the ranks of antituberculosis workers: (3) enlist the services of the family physician in the fight against tuberculosis, thereby turning the dream of early diagnosis into a reality; and (4) make possible the adequate institutional or supervisory care of all open cases. The mass examination of population groups brought about by the present military emergency has already thrown back thousands of early cases to the family physician. The opportunity is at hand. Much of the work is being done for us, if we are ready to take advantage of it.

Unfortunately, there seems to be little or no tendency toward present movements in this direction. The American College of Surgeons refuses to recognize thoracic surgery as a specialty and the Advisory Board for Medical Specialties has no listing for the specialist in lung diseases. Bronchoscopy is still retained under the specialty of otolaryngology. In upstate New York, an effort is even being made to accentuate monopoly by concentrating all chest surgical services for one-half of this state in a single hospital. These organizations and these individuals are using their influence to retard the progress and prevent the spread of applied medical science. How are we going to bring about these changes? Perhaps we must wait until public opinion demands that the medical fraternity perform its duty to the masses. When will this be? After the war? Are we going, because of the momentary diversion of our attention, to fumble one of the

#### **PNEUMONOLOGY**

MILTON SILLS LLOYD, M.D., New York City

THE war, which has brought the tuberculosis I problem vividly into focus for other nations, is now rendering this invaluable service to America. Let no one assume that the defeat of our human enemies is the only or even the greatest benefit that may accrue to us as a result of this world-wide struggle. If this war could bring about a sane, well-organized, and concentrated attack upon tuberculosis, leading to its eventual elimination, a contribution would be made to our future society of far greater value than the defeat of Germany and Japan. At a recent meeting in New York of the state and local tuberculosis committees, Dr. Robert E. Plunkett is quoted as having said that the number of deaths from the disease (tuberculosis) since the United States entered the war was six times greater than the casualties among the armed forces of the country. 1 This is not intended to and does not need to cause the slightest deviation from the full pursuit of military victory. The means to successfully combat tuberculosis are at hand. They should be fully exploited. In the words of Archibald MacLeish, "If the means to cure the ill exist and are not used, the failure is a failure of decision, an inability to choose."2 And to quote from the report of Sir William Beveridge to the British Government, "A revolutionary moment in the world's history is a time for revolutions, not for patching." This is the kind of thinking that is necessary in the realm of tuberculosis.

Competent lay and professional opinion has frequently expressed the belief that tuberculosis can be eliminated in a reasonably short period of time (probably fifty years). Improved living standards have made and will continue to make contributions in this direction. But the knock-out blow must be delivered by the medical profession and its affiliated organizations. Unfortunately, this part of our forces has been maneuvered by circumstances into a position of tactical impotence.

#### The Position of the Enemy

Tuberculosis in any selected community may be looked upon as a two-ring circus (see Diagram.) Ring I, the house-infection group, provides a constant supply of new far-advanced cases to Ring II, the supervised group. In this realm, concentrated work with excellent results has been done, but it is obvious that, regardless of the intensity of activity in Ring II, the situation will remain unchanged until the source of

supply in Ring I is successfully attacked. The question is posed, in other words, of the relative importance of preventive and therapeutic activities.

Great progress has been made in this century in the fields of diagnosis, classification, and medical and surgical treatments. Unfortunately however, the mistake has been and continues to be made of employing the same standards and methods in the field of public health. The effort is bound to be futile. Health authorities must work out a classification based upon the case relation to public health interests. This should present no difficulty, since all the elements are known and understood.

#### Current Policies Outmoded

When Trudeau demonstrated the value of test a new era of hope was opened for the tuberculosis sufferer. It was, however, not an unmitigated gain.

The general hospital, long embarrassed by the tuberculosis problem, shifted its burden with a sigh of relief to the rapidly developing crop of country sanatoria. In quick succession, medical boards of general hospitals all over the country inserted clauses in their constitutions prohibiting the admission of tuberculosis cases to, or their treatment in, general hospitals. This move denied all opportunity for training to the general practitioner, without whom there can be no hope of early diagnosis. The specialty of tuberculosis became a monopoly exploited by a small army of workers in which everyone is a general and there are no soldiers. It eliminated the possibility of ever rendering adequate service to the public in the tuberculosis field, because the services which reach the public (institutional and personnel) are excluded in advance. Only in large urban centers are found facilities and trained physicians equal to the demand. If the population of the United States is divided on the basis of service to tuberculosis patients, we find that approximately thirty five million may conveniently secure such care; the remaining one hundred million cannot. It is frequently necessary for the patient to travel one hundred miles for such a simple procedure as a pneumothorax refill.

The average general hospital has no chest service at all. The disease and the remedy have become mutually supporting antagonists. Again the effort, as far as its public health aspects are concerned, is destined to futility.

# THE ANESTHETIC MANAGEMENT OF AGED PATIENTS WITH TRACTURED NECK OF THE FEMUR

G. Hershey, M.D., and Evelyn Apogi, M.D., New York City

THE field of geriatrics is steadily widening as the longevity of our population is increased. Between 1900 and 1940, in the United States, here was an increase of fifteen years in the average life expectancy. In 1940, 6.8 per cent of the population was 65 years of age or more, and with the war it is expected that the proportion of aged will continue to rise.

These figures indicate the growing importance of a more careful consideration of this group of patients. Surgery has always been considered a hazardous undertaking in the older individual, and not the least of the dangers involved was anesthesia. Although we cannot control the degenerative changes that are almost invariably present in the patient of advanced years, we can attempt to minimize the physiologic trauma to which he is subjected during anesthesia.

Fracture of the femur is among the more common conditions for which surgery is undertaken for the aged. This condition is peculiarly suitable for an analysis of the older age group, since most of these patients were supposedly not ill prior to the accident, or at least were able to carry on their ordinary duties, and therefore should be representative of a cross section of the older population.

Elderly patients with fracture of the neck of the femur present an interesting problem in management. Within the recent past, fracture of this kind was a catastrophe. There were, of course, attempts at treatment. Even the Egyptians treated this fracture by devising splints. methods of traction, and some type of cast. <sup>1,2</sup> Their results are not known, but may have been good, since no mummies with nonunion have been recovered from their tombs. Ambrose Paré has written on the treatment of this injury. Up to 1905, many types of splints, casts, and operative procedures were reported, but the consensus of opinion was that active treatment was almost hopeless.

In 1905, Royal Whitman crusaded for the application of a plaster body cast after closed reduction of the fracture performed during anesthesia. Before this, 75 per cent mortality was a conservative estimate. Whitman's treatment reduced this figure to an average of 20 per cent.

Modern treatment dates from 1928-1931,

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 4, 1943.
From the Department of Anesthesia, Bellevue Hospital, New York City.

when Smith-Petersen recommended open reduction and internal fixation for fractures of the femoral neck. This work initiated an era in which special equipment and technics are constantly being developed. Closed reduction with internal fixation has naturally followed the open operation. The manipulations are now usually performed with efficiency and dispatch, and only the moribund are refused operation. Mortality, morbidity, and hospital stay have been strikingly reduced, and it is agreed now that no patient need be denied operation because of advanced age.

The successes with this operation, in so far as survival is concerned, are dependent to a large extent upon the advances made in pre- and postoperative care and anesthetic management. Although the tendency toward early operation is growing, surgery is generally delayed until the patient's condition is satisfactory or improving. Shock is treated. Fluid-electrolyte balance, cardiac and renal status are appraised and appropriately handled. This care is extended to the postoperative period. The objective is to bring the patient to operation in optimum physiologic state, perform the operation, and maintain this condition postoperatively. Most critical is the period of anesthesia and operation. The management of this period is the problem of the anesthetist. With the clearer understanding of the pharmacology of anesthetic drugs and their effects in the presence of organic and functional disturbances so prevalent in the aging patient, and the improved methods for anesthesia. the hazards of surgery and postoperative complications have been minimized.

The elderly person frequently presents special problems, and no one routine is certain to meet all requirements. Preoperative complications are considered in the evaluation of the patient's physical status, and specifically influence the choice of anesthetic agent and technic. The various problems the anesthetist must solve satisfactorily might be listed. These are: (a) pain relief, (b) protection against uncomfortable positions and restlessness, (c) adequate muscular relaxation, (d) maintenance of normal physiological functions, especially in the presence of complications, (e) possibility of explosions with x-ray apparatus.

Brief consideration will be given to the inhalation, regional, and other groups of drugs to indicate the trend of reasoning taken in their selecgreatest opportunities ever placed in the hands of American medicine?

#### Summary

- 1. We know how to prevent and how to treat tuberculosis. Our failure to make better progress lies in a faulty organization—an "inability to choose."
- 2. The burden of complaint of the tuberculosis worker in the past has been late diagnosis and insufficient hospital beds.
- 3. The early diagnosis problem is being solved for us to a large extent as a by-product of the war. It can be completed by enlisting the services of the general practitioner and the "bed" problem can be met by carrying the work to the people in the general hospital and the home.
- 4. The intensity of medical activity must be equally divided between the fields of therapeutic and preventive medicine. A new classification of tuberculosis, based on public health requirements, must be worked out. On this basis, there should be an intensification in the application of provisions of the sanitary code to tuberculosis cases by health authorities and, if necessary, an increased allocation of power to them.
- 5. To accomplish this, the general practitioner must be given training in tuberculosis and

- a share in antituberculosis work equal to the part which he plays in other fields. The lung specialist must be given the opportunity of rendering his service to, and earning a living in, a small community.
- 6. A new specialty, "pneumonology," including all the modern methods of diagnosing and treating thoracic disease, must be established and gradually built up in every general hospital. This does not increase the tendency toward specialization. It would, on the contrary, turn the three "specialties"—tuberculosis, bronchoscopy, and thoracic surgery—into one and give them their proper deployment in organized medicine.
- 7. This would carry the antituberculosis work to all the people and a full-scale, nation-wide campaign would then be under way.
- 8. The greatest opportunity likely to occur in this century is with us at this moment. By intelligent organization we can win a resounding victory in this field without the expenditure of any money and without diverting our attention in any degree from the war effort.

#### Announcement

#### 1944 ANNUAL MEETING

Medical Society of the State of New York

The 138th Annual Meeting of the Medical Society of the State of New York will be held Monday, May 8, to Thursday, May 11, 1944, inclusive, at Hotel Pennsylvania in New York City.

COUNCIL COMMITTEE ON CONVENTION

tient's head and neck with a single wet cotton sheet, which extends downward to the floor. In addition, a closed anesthesia system with carbon dioxide absorber will allow no free gases to reach the atmosphere, and thus further protection is added. While electrical equipment is in actual use no anesthetic agent should be permitted to flow, and before its use the possibility of leaks in the closed system must be entirely eliminated.

Routinely, inhalation anesthesia should be carried out with a closed rebreathing system and carbon dioxide absorption technic. If nitrous oxide-oxygen-ether sequence is contemplated, the induction may be done with semiclosed nitrous oxide technic using 20 or more per cent oxygen plus carbon dioxide absorption. provides a slightly longer, but an entirely nonhypoxic, physiologic induction of anesthesia before ether is added to the system. Deep anesthesia for protracted periods of time should be avoided. Once the fracture has been reduced, the first plane of surgical anesthesia is adequate for the remainder of the surgery. The total amount of agent needed is small if the system is kept free of leaks. At the close of operation, the patient should leave the operating room with all reflexes active.

The technic of spinal anesthesia need not be reviewed. It is advisable to use a hyperbaric drug, such as 5 per cent procaine or 10 per cent pontocaine, in plasma, to aid in keeping the level of anesthesia low.3 To insure this, the table may be tilted slightly, injection made low and slowly, and if possible with the patient on the side with the fractured limb lowermost. Should the tap be impossible in the midline because of skeletal changes or lack of flexion, it may be feasible from the lateral sacral approach. It is advisable to have a sympathomimetic drug such as ephedrine or neosynephrine at hand, should the blood pressure fall rapidly and the pulse pressure become small. This precaution is of considerable importance in hypertensive patients, whose circulatory systems are more sensitive to rapid blood pressure fluctuations. In o'der persons it is safer to give repeated small doses of adrenergic drugs, rather than a single large dose. In the presence of intercostal paralysis or nausea and retching, oxygen by mask or nasal catheter is often beneficial. To add to the patient's comfort, the eyes should be covered with a cool moist piece of gauze, and the ears plugged with absorbent cotton. A small soft pillow under the head is helpful. The anesthetist should remain with the patient at all times, and make his presence known. This is a reassurance the patient deserves. It may often be advisable to provide enough inhalation anesthesia with one of the gases to produce unconsciousness,

The role of preoperative sedation cannot be overemphasized. Morphine and scopolamine in the ratio of 1:25 is ordinarily a good choice. Dosage should be moderate to avoid the excessive depression so easily obtained in the elderly. Morphine should be given cautiously to diabetic and asthmatic patients. A short-acting barbiturate may be added for apprehensive patients. Recent observations suggest the use of Demerol in place of morphine. A dose of 50 to 75 mg. provides adequate sedation with little evidence of respiratory depression.

An infusion should be started before operation or be immediately available in the operating room. Five per cent glucose in normal saline should be given slowly. If shock is impending, plasma or whole blood are preferable, the latter more so if blood loss is significant and anemia was present preoperatively.

At the time of the reduction of the fracture a reflex fall in blood pressure occurs occasionally. In this event, it is wise to ask the surgeon to stop the maneuver. Recovery is usually prompt. If not, or if the reflex recurs, small amounts of ephedrine may be given intravenously. In any event, the blood pressure should not be allowed to remain low, regardless of the pulse rate, for more than a brief period. It is more discreet to postpone the procedure when a period of waiting, drugs, and intravenous fluids do not improve the situation. A rare complication, which should be borne in mind when an old fracture is reduced, is the occurrence of fat embolism.

This report analyzes anesthesia for the Smith-Petersen nailing type of operation for fractured neck of the femur. All patients were over 60 years of age. For the most part, the actual surgery was done by members of the resident staff. and anesthesia was selected and administered by resident anesthetists of varied experience. The patients themselves were not well-cared-for old people, but were typical of the elderly patients admitted to a large municipal institution caring for indigent patients exclusively. With the tendency to treat these fractures as emergencies there was frequently inadequate psychic and medical preparation of the patient. No consideration has been given the functional results of surgery. The material has been grouped for presentation into four categories: (1) distribution of patients by age, sex, and physical status. (2) complications: preoperative, operative, and postoperative, (3) anesthesia, and (4) analysis of deaths.

Chart 1 summarizes the distribution of cases. In all there were 173, whose ages are broken down into ten-year periods; 42 per cent were males. The preoperative physical status was based on

tion, rather than to review the pharmacology of each comprehensively.

Nitrous oxide can be administered safely and satisfactorily. It must be avoided when sufficient relaxation cannot be achieved without some degree of hypoxemia. This cannot ordinarily be expected without fairly heavy preoperative sedation, which has its drawbacks in elderly people. In debilitated patients with flabby musculature, and in those who can be brought to the operating room with metabolic activity so depressed that the surgical requirements can be met without decreasing oxygen tensions, it is a good choice. It is vital that any degree of oxygen deficiency be avoided in the presence of hypertension, arteriosclerosis, and cardiac disease. This precaution applies equally well when nitrous oxide is used for induction of ether anesthesia. Nitrous oxide-oxygen mixtures are often satisfactory as complementary agents when regional or basal anesthesia is used.

of pre-existing systemic frequency disease requires that ether be used with caution. When a patient has diabetes, the use of ether is often avoided because of its tendency to increase blood sugar and produce ketosis. An anesthetic less stimulating to mucous secretion may aid in bringing about a smoother postoperative period in patients with bronchitis and emphysema. Diminished renal function, commonly evidenced by albuminuria, especially in hypertensive and arteriosclerotic patients, suggests cautious use of ether, which causes changes in renal epithelium. Where liver function is questionable the same precaution applies. Ether may often be the agent of choice for patients with heart dis-

Cyclopropane has many advantages for this group of patients. It does not alter blood sugar and is safe for diabetics. The liver and kidneys are not significantly affected. Secretion of mucus in the tracheobronchial passages is minimal. In addition it affords rapid induction and the period of recovery is short. The conducting mechanism of the heart, however, is sensitized by cyclopropane; this agent must be avoided in the presence of cardiac arrhythmias. digitalized patient should be given cyclopropane with extreme caution. Asthmatic patients should be watched carefully, as this agent has a parasympathomimetic effect and has caused severe bronchial constriction. The use of epinephrine should be avoided during cyclopropane

Local infiltration, if done properly, will secure pain relief at the operative site. Complete muscular relaxation, however, may not always be obtained. Excessive sedation is likely to be required. Pain, restlessness, and agitation may not only lengthen the operative procedure, but may become a factor in the onset of shock. There are some stolid patients to whom these objections do not apply.

Spinal anesthesia will provide muscular relaxation but the patient is still conscious and may become restless and disturbed. In cases of hypertension and decreased cardiovascular function, the frequently associated hypotension may embarrass the circulation. There can be no absolute guarantee that the level of spinal anesthesia will be, or will remain, "low," and sympathetic paralysis and reduced intercostal activity may result in both blood pressure fall and decreased ventilation. The use of "heavy" solutions, obtained by the addition of glucose or blood plasma helps to insure a low anesthetic level. The con tinuous technic, although more cumbersome affords a greater margin of safety, in that the drug can be given in small doses. The presence of the traction splint and arthritic changes in the aged patient offer mechanical difficulties in doing the spinal puncture.

The use of avertin in amylene hydrate should be mentioned. This drug is a basal anestheti and must be followed by an additional agent Postoperatively, because of its slow detovition tion, there is a more prolonged period of slee and inactivity, which is not desirable in the el derly patient, since this predisposes to respira tory morbidity. It is administered in a singl total dose and cannot be removed, should an untoward effect ensue. In addition, because is conjugated with glycuronic acid in the live and eliminated by the kidneys, it imposes som burden on these organs. Avertin exerts a di pressant effect on respiration, which is ofter times significant. It may also cause a marke depression of the arterial tension.

The use of intravenous anesthesia with the rapidly acting thiobarbiturates presents several similar drawbacks. It does not invariably provide good muscular relaxation, depresses respiration, and must be detoxified in the body. It use has not generally been advised for length procedures in elderly patients, as the total dosagrequired may be relatively large. Combination of several agents probably adds no safet to this operative procedure.

The technics of administration must meet the patient's requirements, plus those specific to the operation. Regional, rectal, and intravenous anesthetics possess the advantage of being not inflammable or nonexplosive. Inhalation agen are either inflammable, explosive, or aid combution. X-ray equipment is part of the surgic setup. Along with the usual precautions again static charge, additional protection may be so cured by draping the anesthesia machine and pages.

#### CHART 5 .-- ANESTHESIA

Inhalation	Number
Nitrous oxide-oxygen-ether	42
Cyclopropane Ethyl chloride-ether	70
Ethyl chloride-ether	1
Crolone	Š
•	Š
•	\$ 5
	131
Regional	
Spinal	11
Local	26
	37
Combined	31
Spinal and inhalation	1
Local and inhalation	- 3
Total	173

The postoperative complications, in order of frequency, were vomiting, cardiac failure, pneumonia, cough, arrythmia, headache, urinary retention, tachycardia, and distension. The frequency of each was surprisingly low. One hundred and twenty-five patients, or 72.2 per cent, had no postoperative complications.

Chart 5 considers anesthesia. All inhalation agents, except in one case, were administered by the to-and-fro carbon dioxide absorption technic. Inhalation anesthesia was chosen 131 times, or in 76.1 per cent of the cases, and regional anesthesia in 37 or 21.4 per cent. Four patients who had been given local infiltration and one spinal anesthesia required complementary inhalation anesthesia. As noted, cyclopropane was used as the sole agent 70 times, or in 53 per cent of all inhalation anesthesias. The frequency of use of any agent is not intended to indicate its relative merits, but rather the number of instances in which it was the agent of choice.

In Chart 6 deaths are tabulated. There were 11, or 6.3 per cent. The ages varied from 60 to 91, and averaged 73.5 years. Three were males and eight were females. Five were classified as having fair, and six poor physical status. Of the fatalities, four received nitrous oxide-oxygenether, one cyclopropane, and six local infiltration anesthesias. The total mortality in the inhalation cases was 3.7 per cent, and in the regional cases 16 per cent. The physical status of those who received inhalation anesthesia was recorded as poor for two, and fair for three. Of the fatalities in the local infiltration group four were classed as having poor, and two as having fair physical status.

Causes of death were few. One patient died of shock, evident during operation. Four died of circulatory causes, three of cardiac failure, and one of coronary occlusion. Four patients died of pneumonia, one case of which occurred in a lung extensively infiltrated with carcinoma. Two patients became "toxic," lapsed into coma, and died.

#### Summary

This report is an outline of the anesthetic management, and a summary of results from following it, in 173 cases. In previous reviews of this procedure, when anesthesia is mentioned. it is usually to list the agents or technics the surgeon has used or considers preferable. These include spinal or local infiltration, nitrous oxide, morphine, paraldehyde, ethylene.6 Ether was rarely recommended and cyclopropane not mentioned. Operative mortality has been reported variously from 1 to 17 per cent, usually averaging between 5 and 10 per cent. This is considerable improvement over conservative therapy, which still carries a 20 per cent average mortality. In this series all fatalities averaged 6.3 per cent, and what seems striking is a 3.7 per cent death rate for those cases done with inhalation anesthesia. These seem to be good results in what has been termed the simple fracture with the highest death rate in middle or old age.

Frequently, when confronted with a patient in poor condition, the surgeon tends to choose regional anesthesia as the safer procedure. While a definite answer is not intended to be found in this report, some deductions seem reasonable. With careful anesthetic management, operation under inhalation anesthesia was well tolerated by these elderly people. There were no deaths in the operating rooms. Postoperative morbidity was low and the rate of mortality favorable. No attempt was made to select this group for special care or supervision.

In concluding, it should be noted that anesthesia in the aged remains a serious problem. Progress has been achieved by developing general medical care and specific surgical technics. Further improvement is likely if anesthetic management is based on the physiological requirements of the patient, and knowledge of the effects of the anesthetic agents in the presence of preexisting disease. In this group of patients inhalation anesthesia seemed to meet these requirements.

Female	101
Physical Status	101
Good	31
Fair	104
Poor	38

the seven group classification of the Committee on Records of the American Society of Anesthetists. Regrouping these patients for brevity, 31 might be considered to have good physical status, 104 fair, and 38 poor.

Charts 2, 3, and 4 summarize complications, and these are subdivided according to the anesthetic method or agent used. Preoperatively, this age group is associated with a multiplicity of positive physical findings. Grouping cardiac disease, hypertension, and generalized arterioscletosis, 91 per cent had circulatory involvement; 23.1 per cent had pulmonary complications, almost all of which were senile bronchitis and emphysema. Seven had had recent bronchopneumonia; 17.2 per cent had albuminuria, and the incidence of diabetes mellitus was 5.2 per cent. The high incidence of these significant

preoperative findings justifies the surgeon's concern.

The operative complications considered for the study were those that had bearing on the postoperative course. A fall in blood pressure was noted 40 times (23.1 per cent.) Four of these were believed due to reflex effect, five resulted from spinal anesthesia. It must be assumed that a drop in blood pressure not due to reflexes or spinal anesthesia indicates circulatory impairment and eventual approach of shock Shock was diagnosed in 8 cases, or 4.6 per cent, of this group. Diagnosis was purely on clinical standards. Tachycardia without changes in blood pressure occurred 19 times; again this may be considered a possible forewarning of shock. Arrythmia was seen in 9 cases, 5 of which were anesthetized with cyclopropane. Hypoxemia resulting from excessive secretions or laryngospasm occurred in 10 cases. These are significant in that they place an added burden on the circulation. A blood pressure rise was noted in 14 cases. Pain was a complication of eight of the twenty-six patients operated on with local anesthesia, and 1 of the 11 having spinal anethesia. Eighty-eight (50.8 per cent) of the patients had no operative complications, and of these approximately half were anesthetized with cyclopropane.

#### HITLER AND MATHEMATICS

In 1926 the International Education Board, lounded by Mr. John D. Rockefeller, Jr., made an appropriation of \$275,000 to the University of Göttingen in Germany to build and equip a Mathematical Institute. For many decades Göttingen had been an important mathematical center, but the first World War left it impoverished. The new funds in 1926 enabled it not only to add to its physical facilities for mathematical research but to strengthen its already brilliant faculty. In a few years Göttingen became the world's chief center for advanced study in mathematics and physics, and its students arrived in increasing numbers from many countries.

Then the Nazi régime took over Germany, and its effect on Göttingen was drastic and immediate. The Jews on the faculty were thrown out, and their colleagues of Aryan stock, shocked by this intolerance and unable to live in the stifling intellectual atmosphere, resigned. By 1939 only one of the original faculty remained active at the Institute. Most of the others came to the United States.

In view of what has happened in the last few years it seems ironical that this German institution was brought to maturity by American funds. An even deeper irony lies in the fact that the blind fanaticism of the Nazis succeeded in driving to America some of the world's leading mathematicians. There appears to be a universal principle about intolerance: it reacts on those who practice it. Just as many countries were enriched by the Huguenot immigration that followed the revocation of the Edict of Nantes, so the United States and England have greatly profited by the scholarship driven out of central Europe through the self-defeating bigotry of Nazi ideology.

If Hitler had set out, with benevolent intent, to build up America as the world's great mathematical center, he could hardly have achieved more successfully the result which his ruthlessness has accomplished. During the last decade 131 leading European mathematicians have migrated to the United States. Of these, 16 came from the faculty of Göttingen. The School of Advanced Study at Princeton, Brown University, New York University, Harvard, Chicago, the University of Wisconsin, the Massachusetts Institute of Technology are only a few of the American institutions which have profited by this migration.-Rockefeller Foundation Review for 1942

#### Discussion

Charles C. Wells, Syracuse—This is an important though infrequently discussed topic of anesthesia. Dr. Apogi is to be congratulated on her excellent presentation.

With better health and greater life expectancy in those of riper years, it may be necessary to readjust our ideas as to where old age actually begins. Years are a relative measure of age, as the ravages of time seem to be more prominent in some persons than in others. It has been my custom to classify my patients for their anesthetic risk more by their apparent physical age than by their chronologic age.

As a group, the aged take very kindly to anesthesia, and do not require heavy sedation or anesthesia. The smallest amount of anesthetic necessary to satisfactorily relax the muscles and prevent pain reflexes seems to be the optimal amount.

Since it is desirable that aged patients be returned to consciousness and ability to move as soon as possible, I thoroughly agree that it is wise to limit or avoid long-acting sedatives and narcotics. As the aged are easily affected by lack of oxygen, it is necessary to maintain a patent airway and a high percentage of oxygen at all times.

I do not hesitate to use ether, when needed, to deepen anesthesia with nitrous oxide or cyclopropane. It is far safer to do this than to run into ex-

cessive anoxemia with the former, or cardiac complications with the latter, when these anesthetics are pushed too far. Kidney complications from ether may come reflexly through stimulating the nerve endings of the upper respiratory tract. If these reflexes are first obtunded by some nonirritating anesthetic, such as nitrous oxide or cyclopropane, ether may be added with no such irritating effects.

As essential as rules and suggestions may be in the conduct of anesthesia for the aged, there is nothing that can take the place of a trained medical anesthe tist in this particular type of borderline surgical and anesthetic risk. Careful preoperative evaluation of the risk, notation of the patient's previous operative and anesthetic experiences, and reassuring suggestions by the anesthetist not only familiarize the anesthetist with the physical condition of the patient, but also secure the patient's confidence and cooperation.

The Smith-Petersen nailing operation for the fractured neck of the femur is very typical of operations in the aged. Other types of operations on the aged could be studied with profit. We seldom use avertin, intravenous, or spinal anesthesia in this type of case. Our usual technic is to introduce anesthesia with a local anesthetic, and perform the more painful conclusion under nitrous oxide or cyclopropane-oxygen anesthesia. I do not recall a single death in the operating room or a postoperative anesthetic death with this method.

Carefully studied and cared for cases of this group should very seldom be denied the benefits of surgery, which adds so much to the comfort and usefulness of the patient. Anesthetists rejoice in being able to help reduce the morbidity and mortality of this type of case.

#### BRITISH JOURNAL OF INDUSTRIAL MEDICINE

The British Medical Journal announces the publication commencing in January of an addition to the specialist journals published by the British Medical Association—the British Journal of Industrial Medicine. The project has often been discussed in recent years, and the final stimulus to action came in the shape of a formal request to the British Medical Association from the Association of Industrial Medical Officers. An editorial board was formed, and it was intended that Sir Henry Bashford, chief medical officer of the post office, would be editor-in-chief, but his recent appointment as medical adviser to the treasury prevents this. It is anticipated that Dr. Donald Hunter of the London Hospital will take his place. The other editors will be Dr. A. J. Amor, Dr. M. W. Goldblatt, Dr. D. C. Norris, Dr. Donald Stewart, and Mr. R. W. Watson The British Medical Learned and Stewart and Mr. R. W. Watson The British Medical Learned and Mr. R. W. Watson The British Mr. R. W. Watson The British Medical Learned and Mr. R. W. Watson The British Mr. R. W. Watson The British Mr. R. W. Watson The British Mr. R. W. Watson Th Jones, a surgeon. The British Medical Journal says

that since 1939 the country has been overwhelmingly conscious of the extent to which it owes its safety to the health of the worker in industry. Industrial medicine is not just industrial toxicology; in fact, this is but a small part of it. A whole range of problems face the worker, the management, and the doctor-the effect on the worker and his work of temperature and humidity, of the intensity and direction of illumination, of posture and change of posture, of rest pauses and recreation, of washing facilities, of canteens, and of an efficient accident service. There are also the important psychologic problems of monotony, relations between foreman and worker, selection of work, and so on. From industrial medicine a steady flow of observation and research is hoped for, and much of this should find an outlet in the British Journal of Industrial Medicine.

#### ARMY WANTS 1,350 MORE OCCUPATIONAL THERAPISTS

Within the next year, the Army will add 1,350 additional occupational therapists to its staff to aid in the rehabilitation of the wounded. Since only 350 new graduates will enter the field in that period, 1,000 will have to be drawn from civilian life.

The Reconditioning Division, office of the Sur-

geon General, hopes to return every wounded soldier to the highest possible degree of ability, according to Mrs. Winifred C. Kalımann, superintendent of Occupational Therapy. Its threefold program involves physical and mental care and education.—J. Med. Soc. Co. N.Y.

#### Medical News

#### Center for Study of Physical Medicine

THE establishment of the first center for the scientific study and development of physical nedicine as a branch of medical practice was an-nounced on December 15 by Basil O'Connor, president of the National Foundation for Infantile The center will be in the Graduate School of Medicine of the University of Pennsylvania at Philadelphia.

To set up this center, Mr. O'Connor stated the National Foundation for Infantile Paralysis has made a grant totaling \$150,000 for a five-year period from January 1, 1944, to December 31, 1948.

Mr. O'Connor said, "We believe this to be one of

the most important steps which the National Foundation has taken. This will not only advance the treatment of infantile paralysis, but of many other diseases as well."

Mr. O'Connor explained that today there are only a few schools or departments connected with any of the medical training centers which are equipped to explore thoroughly on a sound scientific basis the possibilities of physical medicine.

This is but the first step in a program which, Mr. O'Connor said, should afford a scientific basis for physical therapy and lead to the establishment of a

more desirable teaching program.

"If this branch of medicine can be given a sound professional standing," Mr. O'Connor declared, "medical men of the highest calibre will be attracted to it and practitioners will fully utilize its advantages. If research and study show there is little or no basis for treatment by some of the physical agents, then an equally great service will have been rendered, even though it be principally

negative in character.

"Physical medicine plays a most important part in the treatment of infantile paralysis. Since it was first organized, the National Foundation has been continuously concerned with this phase of treatment. It has spent during the past six years over \$350,000 to educate and train physical therapy technicians. An additional \$364,000 has been granted to laboratories and universities to study many problems in physiology and medicine having a close connection with the practice of physical therapy, but never before has it been possible to combine in one place both medical research and teaching in this important field.'

The Center for Research and Instruction in Physi-

cal Medicine will include:

A center for development of physical medicine as a scientific part of the practice of medicine,

A training center for medical leaders and

teachers in this branch of medicine, and

3. A school for training technical workers under the guidance of such professional and scientific leadership, such a school to be only incidental to and dependent upon the first two purposes

The Departments of Anatomy, Physiology, Pathology, and other basic sciences of the University of Pennsylvania will cooperate in this proposed program. The general direction will be assigned to Dr. Robin C. Buerki, Dean of the Graduate School of Medicine.

#### Neff Is Executive Director of Cancer Society

J. LOUIS Neff, of East Williston, has been appointed Executive Director of the American Society

for the Control of Cancer, effective January 1, 1944.

Mr. Neff has been executive secretary of the Nassau County Medical Society since 1923 and has also been secretary of the Nassau County Cancer Committee since its formation in 1928.

In 1933 he helped to organize the Nassau County Tumor Clinic, now being conducted by Meadow-brook Hospital, and served as its executive director until it was transferred to Meadowbrook from its original location at the Tuberculosis Sanatorium in

Farmingdale.

He has been identified with public health and welfare organizations of the county for many years. He is treasurer of the Nassau County Council of Public Health Nursing, and of the Nassau County Central Index.

He is a director of the Nassau County Tuberculosis and Public Health Association and of the County Nutrition Council. He helped to organize the Emergency Medical Service of the Nassau County War Council and is still a member of its staff. He is also chairman of the Committee on Health and Safety of the North East District of the Nassau County Boy Scout Council.

#### Announcement of the 1944 Examinations of the American Board of Obstetrics and Gynecology

THE next written examination and review histories (Part I) for all candidates will be held in various cities of the United States and Canada on Saturday, February 12, 1944, at 2:00 P.M.

Arrangements will be made as far as is possible for candidates in military service to take the Part I examination (written paper and submission of case records) at their places of duty, the written examination to be proctored by the commanding officer (medical) or some responsible person designated by him.

Material for the written examination will be sent to the proctor several weeks in advance of the examination date. Candidates for the February 12, 1944, Part I examination, who are entering military service, or who are now in service and may be assigned to foreign duty, may submit their case records in advance of the above date, by forwarding them to the office of the Board Secretary. All other candidates should present their case records to the examiner at the time and place of taking the written examination.

The Office of the Surgeon General (U.S. Army) has issued instructions that men in service, eligible for Board examinations, be encouraged to apply and that they may request orders to detached duty for the purpose of taking these examinations when-

ever possible.

All candidates will be required to take both the

# Secondary Anemia

It is now quite generally accepted that in simple secondary anemia no hematinic other than iron is required for its correction. In many instances, however, anemia is accompanied by other signs of nutritional failure. Most frequently encountered is deficiency of the Vitamin B Complex.

In such cases Hebulon\* Capsules (Squibb Liver Extract, Ferrous Sulfate and Vitamin B<sub>1</sub>) offer not only an effective dose of exsic-

cated ferrous sulfate, but supply, in addition, 50 U.S.P. units of Vitamin B<sub>1</sub> and liver extract derived from 16 Gm. fresh liver. The capsules thus provide a convenient means of supplying not only iron, but B complex factor vitamins and hemoglobin - building substances contained in liver extract, which have been shown to be frequently needed in cases of nutritional failure.

Hebulon is supplied in bottles of 100, 500 and 1000 capsules.

For literature address the Professional Service Dept., 745 Fifth Avenue, New York 22, N. Y.

"Hebulon" (Registered in U. S. Pat. Off.) is a trade-mark of E. R. Squibb & Sons.

# E.R. SQUIBB & SONS, NEW YORK MANUFACTURING CHEMISTS TO THE MEDICAL PROFESSION SINCE 1858

Part I examination and the Part II examination (oral clinical and pathology examination). Candidates who successfully complete the Part 1 examination proceed automatically to the Part II examination to be held later in the year.

Headquarters for the Part II examination will be the Hotel William Penn, Pittsburgh, Pennsylvania, from June 7-13, 1944. Notice of the exact time of the examinations will be sent all candidates well in advance of the examination date. Candidates in military or naval service are requested to

keep the secretary's office informed of any change in address.

If a candidate in service finds it impossible to proceed with the examinations of the Board, deferment without time penalty will be granted under a waiver of our published regulations as they apply to civilian candidates.

Applications for the 1944 examinations are closed. For further information and application blanks, address Dr. Paul Titus, Secretary, 1015 Highland Building, Pittsburgh 6, Pennsylvania.

#### Annual Tuberculosis and Health Conference in New York City

THE Annual Conference of the New York Tuberculosis and Health Association will be held at Hotel Pennsylvania on Wednesday, February 2. There will be morning section meetings on tuberculosis, the heart diseases, social hygiene, and dental health in industry. The meeting on the heart diseases will be held at Hotel Governor Clinton.

The luncheon meeting, which will bring all the groups together, will be held in the Grand Ball Room of the Pennsylvania at 12:45 o'clock. The speakers will be Rear Admiral Charles S. Stephenson, (MC), United States Navy, and Sir Gerald Campbell, G.C.M.G., British Minister in Washing-ton and Special Assistant to the British Ambass-

#### A.M.A. Points to Principles Governing Evolution of Medical Practice

THE continuing evolution of medical practice, based on sound experimentation, has been urged repeatedly by the American Medical Association, through its House of Delegates, Board of Trustees, and Council on Medical Service and Public Relations, the Journal of the Association declares in its November 20 issue. In an editorial summarizing the principles to govern the evolution of medical practice, adopted by the Representative Committee of the British Medical Association, the Journal points out that the final recommendations of the British group advocate the same approach to the problem of developing a sound system of medical service to meet the needs of all persons in

a community. The Journal says:
"Elsewhere in this issue appear the principles to govern the evolution of medical practice adopted by the Representative Committee of the British Medical Association and by representatives of many official bodies in Great Britain. This group comprised representatives of general practice, consultant, and specialistic practice, public health, rural practice, medical staffs of provincial non-teaching hospitals, and others. Special emphasis should be placed on the principle that the health of the people depends primarily on the social and environmental conditions under which they work, and that improvement and extension of measures to satisfy these needs should precede or accompany any future organization of medical service. Also fundamental is the principle that the efficiency of any medical service depends primarily on medical and scientific knowledge, which, in turn, is based on medical education.

"The British group establishes the principle that the function of the state should be to coordinate existing provisions, both official and nonofficial, to augment these where necessary, and to secure that they are available without economic barriers. Supplementary to this is the statement that the state should confine itself within these wide limits, invading the personal freedom of both citizen and doctor only to the extent which the satisfaction of these functions demands. The platform of the American Medical Association likewise emphasizes the importance of an agency of the federal government, under which shall be coordinated and administered all medical and health functions of the federal government, exclusive of those of the Army and Navy, and the allotment of such funds as the Congress may make available to any state in actual need for the prevention of disease, the promotion of health, and the care of the sick on proof of such The medical profession has not opposed appropriations by Congress of funds for medical purposes. It asks that the need be shown and that funds be locally rather than nationally administered.

"The British Representative Committee again insists on free choice as between doctor and patient as fundamental to sound medical practice and states emphatically that it is not in the public interest that the state should invade the doctor-patient relationship. It is, no doubt, for this reason that the Representative Committee says that it is not in the public interest that the state should convert the medical profession into a salaried branch of central or local government service."

#### Medical Officer Urges Course in Psychiatry for All Doctors

SHORT intensive psychiatric training courses for physicians are very much in order not only to physicians are very much in order, not only to meet the need of the armed forces for more psychiatrists but also for the tremendous postwar job in this field, Lt. Col. William C. Menninger, Medical Corps, Army of the United States, Neuropsychiatric Consultant, Fourth Service Command, declares in the Journal of the American Medical Association for November 20.
"The second major concern confronting every

physician, both in and out of the Army," Colonel Menninger says, "is the number of psychiatric cases which the war experience has disclosed in our general population. The medical and social implications of this group are beyond our present ability to estimate.

"The third major problem confronting the army psychiatrist is the rapid and most effective dis-position of these maladjusted individuals in the

Army. The first purpose of the Army is to win the war, and consequently these soldiers unfit for service must be given over to the care of civilian agencies and civilian physicians with the hope that they will accept the responsibility and provide treatment for these men in accordance with our most modern psychiatric concepts.

The psychiatric problems of the Army, Colonel Menninger explains, "should be of vital interest and concern to every citizen interested in the war effort and particularly to medical men. They should be of interest, first, because of the great number of men whose army experience has brought to light their need for medical and particularly psychiatric help. This fact may be vividly portrayed by these figures: an average of 8 to 10 per

cent of men examined for military service are rejected for psychiatric reasons, and nearly 30 per cent of the discharges from the Army are for psychiatric reasons. In contrast, only 2 per cent of the medical profession are psychiatrists. The social implication of these figures is enormous, but their importance to the medical profession is even greater.

"Every internist is aware of the fact that even in normal circumstances in our prewar practice between 40 and 60 per cent of the patients seeking medical help present only functional disturb-

The Colonel points out that, despite the lack of trained psychiatrists and the lack of facilities, the caliber of neuropsychiatry practiced in the Army is surprisingly good.

#### Albany County

Albany Medical College graduated its first class of "GI doctors" on December 23, when seniors who have been studying in the Army Specialized Training Program and the Navy V-12 Program completed requirements for their degrees.

Twenty-four men in the 3,210th Service Command Service Unit, commanded by Lt. D. J. Sterlinske, were commissioned first lieutenants in the Medical Corps Reserve and have left to serve internships. On completion of intern training they will be called

to active duty. The men who are completing their training were commissioned second lieutenants in the Medical Administrative Corps Reserve when they entered medical college. However, at the request of the government they resigned their commissions to be

assigned in the training program as privates.

Ptc. John Eckel, of Albany, has been awarded the
S. Oakley Vander Poel Prize for the senior making the best bedside examination in general medicine.

The Alumni Association medal for a member of the graduating class whose qualities give promise of typifying the ideal alumnus was awarded to Pfc. John K. Shearer, of Rock Tavern.

Pfc. Paul Former and Pfc. David Gelbard, freshman training students, were awarded prizes for preparing the best anatomic specimens.\*

Dr. John B. Horner has been elected president of the Albany County Medical Society, succeeding Dr. Morgan O. Barrett.

Others elected included Dr. Arthur J. Wallingford, vice-president; Dr. Homer L. Nelms, secretary; Dr. Frances E. Vosburgh, treasurer; and Dr. Emerson C. Kelly, historian.

Dr. Barrett, the retiring president, was named chairman of the board of censors, which will be composed of Dr. John J. Clemmer, Dr. Edward P. McDonald, Dr. Donald D. Prentice, and Dr. Clarence Traver.

Delegates to the State Convention are Dr. Nelms, Dr. James Lyons, and Dr. Stanley E. Alderson, Alternate delegates are Dr. Raymond F. Kircher. Dr. Earle W. Wilkins, and Dr. Jacob L. Lochner, Jr.\*

Dr. George M. Glann has closed his office at Fonda where he has practiced for several years and will locate at Albany.

#### Broome County

At the annual dinner meeting and election of officers of the Broome County Medical Society, held December 14, 1943, the following officers were elected for 1944: president, Dr. Frank G. Moore, Endicott; vice-president, Dr. Victor W. Bergstrom, Binghamton; secretary, Dr. J. C. Zillhardt, Binghamton; assistant secretary, Dr. A. L. Standfast, Binghamton; treasurer, Dr. Leonard J. Flanagan, Binghamton; and assistant treasurer, Dr. Ralph C. Goudey, Binghamton.

Chairmen of committees are: legislative, Dr. George C. Vogt, Binghamton; public relations, Dr. Charles M. Allaben, Binghamton; public health, Dr. Ralph M. Vincent, Binghamton; milk commission, Dr. Perry H. Shaw, Binghamton; library, Dr. Stuart B. Blakely, Binghamton; membership, Dr. Ralph J. McMahon, Johnson City.

Elected to the Compensation Board for a term of three years are Dr. George W. Danton, Endicott; Dr. Ralph C. Goudey, Binghamton; and Dr. Charles M. Woodburn, Binghamton.

The board of censors consists of Dr. J. J. Cunningham, Binghamton; Dr. Walter J. Farrell, Johnson City; Dr. H. I. Johnston, Binghamton; Dr. A. J. Stillson, Binghamton; and Dr. George C. Vogt,

Binghamton. Delegates to the State Society are: Dr. Victor W. Bergstrom, Binghamton, and Dr. H. I. Johnston,

Binghamton. Dr. Elton R. Dickson, Alternate delegates: Binghamton, and Dr. George C. Vogt, Bingham-

Cattaraugus County

Ellicottville's oldest doctor and one of Western New York's oldest practicing physicians, Dr. Charles M. Walrath, observed his eighty-eighth birth-day at his home on December 5. He was the recipient of a shower of congratulations and many birthday cards and gifts.

Dr. Walrath has been actively engaged in the practice of medicine in his community for over sixty

A former mayor of the village, he has also served on the school board and held other public offi-

He is well known in county medical circles and is a member of the Cattaraugus County Medical Society.\*

AN Effective BARRIER

ompetent clinical investigation has established the effectiveness of a properly fitted occlusive diaphragm. Attention, however, should be directed to the need of not only providing for the protection but also the comfort of the patient, in order to assure continued use of the diaphragm.

Examination of the "RAMSES" Flexible Cushioned Diaphragm reveals that:

- 1. The dome is made of velvet-soft pure gum rubber. It will not induce irritation.
- 2. The patented rim construction provides a rubber cushion which inhibits discomfort from spring pressure and provides a broad unindented surface for contact with the vaginal walls.
- 3. The coil spring used in the rim is flexible in all planes permitting adjustment to muscular action.

A carefully controlled manufacturing process builds lasting qualities into the "RAMSES" Flexible Cushioned Diaphragm. With proper care it will give long service.

"RAMSES" Flexible Cushioned Diaphragms are available in sizes from 50 to 95 millimeters in gradations of 5 millimeters. They are carried in stock by all reliable pharmacies.

Complete professional information will be sent to physicians on request.

#### Cayuga County

Dr. Harold G. Muller has arrived in the village of Cato to start the practice of medicine.

Dr. Muller has been practicing in Lysander, where he has made his home for four and one-half years. He came there directly from a small town in Germany, after Hitler and his Nazis took over the country.

Dr. William R. Johnson, who served the community for thirteen years, has been a naval lieutenant for more than a year. For that period there has been no doctor residing in Cato.\*

#### Chautauqua County

Lt. Comdr. Donald R. Nelson, first Jamestown physician to see active duty with the Navy, distinguished himself when the Marines took the atoll of Tarawa in the Jap-controlled Gilberts, the bloodiest battle in all Marine history, according to an announcement from the Pacific war zone by the Associated Press.

Commander Nelson, with Lt. Comdr. George Stanberry, of Vandalia, Illinois, headed a temporary hospital set up on the beach after the first landings and worked for many hours in caring for the wounded

and dying.

The hospital in charge of the Jamestown physician, according to the dispatch, was set up under fire and operated during the terrible seventy-six hours it took to take the island and kill off 3,000 Japs.\*

#### Chenango County

At the annual meeting of the Chenango County Medical Society, held at Norwich, New York, on December 14, 1943, the following officers were elected for 1944: president, Dr. Edwin F. Gibson, of Norwich; vice-president, Dr. Archibald K. Benedict, of Sherburne; secretary and treasurer, Dr. John H. Stewart, of Norwich.

The following committee chairmen were appointed: legislative, Dr. Jaynes M. Crumb, of South Otselic; economics, Dr. Edward Danforth, of Bainbridge; public health and education, Dr. Leslie T. Kinney, of Norwich; subcommittee on tuberculosis, Dr. A. K. Benedict; maternal welfare, Dr. Carl D. Mascham of Greene; council or medical Dr. Carl D. Meacham, of Greene; council on medical service and public relations, Dr. Albert H. Evans, of Guilford.

Members joined the Rotarians for lunch at the

Chenango.

The physicians were addressed by Dr. Wallace B. Hamby, of Buffalo, professor of neurologic surgery and assistant professor of neurology at the University of Buffalo School of Medicine. His

subject was neurologic surgery.

The Kenny hot-pack was demonstrated to the physicians by Miss Ruth Griffin, state orthopaedic nurse. Miss Louise Campbell, field demonstrator of tuberculosis and public health in Chenango County, also addressed the physicians briefly.\*

#### Cortland County

At the annual meeting of the Medical Society of the County of Cortland, held on December 17, 1943, the following officers were elected: president, Dr. R. P. Carpenter, Cortland; vice-president, Dr. D. B. Glezen, Cincinnatus; secretary, Dr. W. A. Wall, Cortland; and treasurer, Dr. F. F. Sornberger,

The constitution and by-laws with the corrections made by the council at their meeting of October 14, 1943, were adopted by the society.

The president announces the following committee

appointments: Compensation-Arbitration: appointments: Compensation-Arbitration: Dr. Sornberger, chairman; Dr. C. J. Kelley, Cortland; Dr. J. E. Wattenberg, Cortland; legislation: Dr. Wall, chairman; Dr. Hugh Frail, Marathon; Dr. Hans Hirsch, Cortland; and Dr. A. V. Runfola, Cortland; public health: Dr. C. E. Chapin, Cortland, chairman; Dr. E. K. Alexander, Homer; Dr. Glezen; and Dr. R. P. Higgins, Cortland; public relations: Dr. D. R. Reilly, Cortland, chairman; Dr. O. A. Bennett, McGraw; Dr. P. W. Haske, Homer: and Dr. S. A. Ver Noov. Cortland. Homer; and Dr. S. A. Ver Nooy, Cortland.

#### Erie County

The 100th anniversary of the birth of Dr. Robert Koch, discoverer of the tuberculosis bacillus in 1882, was observed in Buffalo's Museum of Science on December 11, 1943, with a talk by Dr. David K. Miller, head of the department of medicine and laboratories in Meyer Memorial Hospital.

The talk was supplemented by exhibits, which were on view throughout the month of December. Sponsoring organizations were: the Academy of Medicine; the Department of Health of the Museum of Science; the Tuberculosis Conference Committee; the Erie County Medical Society; the State Department of Health, Buffalo District; the University of Buffalo School of Medicine; and the Buffalo and Erie County Tuberculosis Association.\*

#### Essex County

The annual meeting of the Medical Society of the County of Essex was held October 5 in Eliza-

bethtown, New York.

Dr. Joseph P. Garen, of the State Health Department, was guest speaker and discussed the plan under which federal money is allocated for maternity care of service men's wives. The society voted to give tentative acceptance to the plan until July

to give tentative acceptance to the pair and 1, 1944.

The following doctors were elected officers for the year 1944: president, Dr. G. L. Knapp, Ticonderoga; vice-president, Dr. Robert Gray, Westport; secretary and treasurer, Dr. J. E. Glavin, Port Henry; censors: Dr. Samuel Volpert, Lake Placid; Dr. Albert Hayes, Willsboro; Dr. T. J. Cummins, Mineville; delegate to the State Convention, Dr. Joseph Geis, Lake Placid; alternate delegate to the State Convention, Dr. T. R. Cummins, Ticonderoga; delegate to the Fourth District Branch, Dr. Samuel Volpert, Lake Placid; alternate delegate to the Fourth District Branch, Dr. Violet McCasland, Moriah. Dr. Violet McCasland, Moriah.

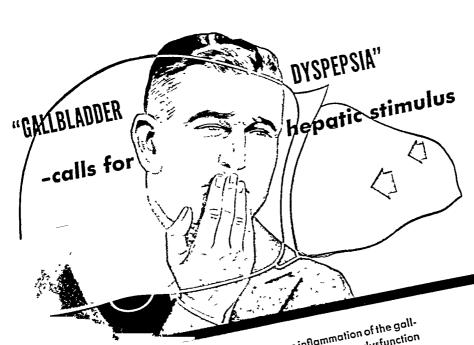

#### Greater New York

Because available information on pertinent as pects of medical practice in Greater New York is either out of date or incomplete, the subcommittee on medical services of the Mayor's Committee on Medical Care, of which Dr. J. Stanley Kenney is chairman, has drafted a questionnaire to be sent to physicians in the city. It is hoped that all recipients will answer and return it promptly.

The information desired touches principally on the distribution of specialties, the time spent in private practice and free service, the patient load per physician, the professional affiliations of physi-cians, medical income, and medical interest in salaried positions.

#### Greene County At the annual meeting of the county society,

[Continued on page 198]

HETHER biliary stasis arises from inflammation of the gallbladder, or of the biliary ducts, or from liver dysfunction -mere emptying of the gallbladder (through cholagogic therapy) cannot provide adequate relief. The liver itself must produce more bile ... fluid enough to pass the biliary channels

Cholan DH (dehydrocholic acid-Maltbie) is a hydrocholeretic of maximum efficiency—increasing from 2 to 4 times the with free and effective drainage. Now of especially low-viscosity bile. Its use may frequently forestall the necessity for surgical intervention by discouraging gall stone formation or the entrenchment of infection. Contra-indications: Occlusive obstruction of biliary tract.

Use with caution in acute yellow atrophy, acute hepatitis,

eclampsia and progressive jaundice.

COMPREHENSIVE

Cholan DH is supplied in bottles containing 100, 500, and 1,000 tablets of 33/4 grains each. Also in ampul form, as Cholan DH Sodium (Solution Sodium Dehydrocholate)—a 20% concentration in 3 cc. or 10 cc. ampuls, 6 of either to a box.

held on October 28, 1943, the following officers were elected: president, Ray E. Persons, of Cairo; vice-president, Edwin G. Mulbury, of Windham; secretary, William M. Rapp, of Catskill; treasurer, Mahlon H. Atkinson, of Catskill; delegate to the State Society, Kenneth F. Bott, of Greenville.

#### Herkimer County

Dr. Dominick F. Aloisio, of Herkimer, was elected president of the Herkimer County Medical Society at its 137th annual meeting held on December 15.

at its 137th annual meeting held on December 15. He succeeds Dr. Byron G. Shults.

Other officers named were: first vice-president, Dr. F. M. Neuendorf, Mohawk; second vice-president, Dr. Brian J. Kelly, Frankfort; third vice-president, Dr. Charles Lanning, Herkimer; librarian, Dr. G. S. Eveleth, Little Falls; secretary, Dr. Fred C. Sabin, Little Falls; treasurer, Dr. Albert L. Fagan, Herkimer; board of censors: Dr. F. H. Moore, Herkimer; Dr. Sabin, Dr. Harold Buckbee, Dolgeville; Dr. H. J. Sheffield, Frankfort; and Dr. C. C. Whittemore, Ilion.

Dr. Aloisio. by virtue of his office, was chosen

Dr. Aloisio, by virtue of his office, was chosen delegate to attend the State Medical Society's annual convention. Dr. Neuendorf was named first

alternate delegate.

Dr. Aloisio named the following as members of his executive committee: Dr. B. G. Shults, Dr. F. J. Moore, and Dr. L. P. Jones, Ilion; Dr. George J. Frank, Frankfort; Dr. Sabin, and Dr. A. B. Santry, Little Falls.

Following the annual custom, the meeting was devoted to a lecture on old-time practices of medicine, this year's essay being given by Dr. Eveleth on "Medicine in Retrospect over Fifty-five Years."

Under terms of the will of Dr. A. W. Suiter, who left a legacy to the medical society, that group must devote at least one meeting each year to medical practices.

A turkey dinner completed the session.\*

#### Jefferson County

Dr. L. L. Samson, president of the county society, has appointed the following committee chairmen: public relations, Dr. Joseph D. Olin, Watertown; program, Dr. Edwin W. Roberts, Watertown; legislative Dr. Horeld I. Colonia, Marchael C. L. Alexandria, Physical Research (1997). tive, Dr. Harold L. Gokey, Alexandria Bay; public health, Dr. Sumner E. Douglas, Adams; economics, Dr. Harlow E. Ralph, Belleville; cancer, Dr. Frederic R. Calkins, Watertown.

Dr. Roger F. Hisey, of Gouverneur, has made arrangements to take over the practice of Dr. Terry Montague in Adams.

Dr. Hisey practiced medicine in Antwerp until Pine Camp expansion took over a large part of the

territory when he moved to Gouverneur.

Dr. Montague is now city health officer in Water-

A native of Henderson, he came to Adams in June, 1942, from St. Lawrence County and took up the practice of Dr. Carl B. Alden, who was called into the service.

Dr. Hisey is a native of Canada, a graduate of the

University of Toronto, class of 1926.

#### Kings County

A stated meeting of the county society was held on December 21, at which time Lt. Col. Thomas T. Mackie, (MC), Executive Officer of Tropical and Military Medicine of the Army Medical School in Washington, D.C., spoke on "Tropical Diseases in the Postwar Practice of Medicine and Surgery." His address was illustrated by lantern slides.

Election of officers was held at this meeting. The

list of officers will appear in a later issue.

The annual meeting of the Associated Physicians of Long Island will be held on Saturday, January 29,

1944, at the Long Island College Hospital The clinical and scientific program will be provided by members of the staff of the Long Island College Hospital. There will be clinics in the morning and a scientific session in the afternoon, at which four short papers will be presented. The annual dinner will be held at 6:30 p.m. at the Brooklyn Club. An interesting after-dinner speaker will be present.

The following lectures will be given, in cooperation with the Brooklyn Institute of Arts and Sciences and the Medical Society of the County of Kings and the the Medical Society of the County of Kings and the Academy of Medicine of Brooklyn, at the Brooklyn Academy of Music, Music Hall, at 8:15 P.M.:
January 14—"Progress of Medicine in War," by Col. C. M. Walson, M.D., 2nd Service Command; January 21—"Germs and Germ Fighters," by Benjamin W. Carey, M.D., assistant director, Lederle Laboratories; January 28—"The Chemist Looks at Medicine," by William M. Malisoft, M.D., New York City; February 4—"Medicine Takes to the Air," by Louis H. Bauer, M.D., Hemostead, Long Island. Hempstead, Long Island.

A membership card will admit two persons. An institute membership card likewise will admit

two.

#### Lewis County

Dr. Walter Neufeld, formerly of New York

City, has opened an office in Copenhagen.

Dr. Neufeld was born in Vienna, Austria, in 1903. He received his medical education in the medical school of the University of Vienna. He was graduated in 1929, and served two years' internship at General Hospital, Vienna. For nine years he had his own office as general practitioner. In 1939 he left Vienna for England, where he remained until May, 1940. He came to the United States in May 1940, and served one year's internship at Goldwater Memorial Hospital, Welfare Island, New York. For the past year he has been executive physician and admitting data. tive physician and admitting doctor.\*

#### Livingston County

Dr. Earle B. Mahoney, assistant professor of surgery at the University of Rochester, addressed members of the Medical Society of the County of Living at the County of the Livingston at their annual meeting held at Big Tree Inn, Geneseo, Monday, December 20. Dr. Mahoney spoke on the topic, "The Treatment of Burns and Experiences at the Cocceput Grove Burns and Experiences at the Cocoanut Grove Disaster."

Dr. Glenn J. Doolittle, of Sonyea, president of the society, presided at the business session, at which new officers were elected. Dinner was served

at 6:15 p.m.

The names of the officers for 1944 will be published in a later issue.

#### Monroe County

Dr. Alexander Brunschwig, professor of surgery at the University of Chicago, addressed the December meeting of the Rochester Academy of Medicine, which was held at 8:45 P.M. on December at the Academy.

His subject was "The Surgery of Pancreatic

Tumors."

Dr. G. Kirby Collier discussed "A Balanced Personality" at a young people's meeting in Rochester on December 5. Dr. Collier is president of the Medical Society of the County of Monroe.\*

A Navy medical officer, returned from combat, spoke at the 123rd annual meeting of the Medical Society of the County of Monroe at the Rochester Academy of Medicine on December 21.

Lt. Comdr. Richard A. Cupaiuoli, (MC), USNR, of the U.S. Naval Hospital, Sampson, gave a talk on "Problems of Medical Officers of the Navy in

Amphibious Operations."

Medical personnel of the armed forces on duty

in the area were invited to attend.

Miss Veronica Maher, executive director, Rochester Chapter, American Red Cross, spoke on "Emergency Liaison Between Doctor and Red Cross." Alvah G. Strong, chairman of the Food Panel, of the OPA, addressed the society on "Food Rationing and Its Relationship to the Doctor."

Officers for 1944 were elected and Dr. Benedict J. Duffy, physician-in-chief, St. Mary's Hospital, who was president-elect, was inducted into office.

A dinner at the University Club at 6:30 P.M. pre-

ceded the meeting.

A list of the officers elected at the meeting will appear in a later issue of the Journal.\*

#### Nassau County

Maxim Brettler, M.D. has opened an office in Great Neck for the general practice of medicine.

Dr. Brettler was born in Poland and was educated in Germany and Switzerland. He served his in-ternship at Sydenham Hospital and was resident physician at the Park West Hospital in New York City.

#### New York County

The monthly meeting of the county society was held on December 27 at 8:15 P.M. at the New York

Academy of Medicine.

The program, arranged and prepared under the auspices of the Tuberculosis Committee of the New York Tuberculosis and Health Association, was as follows: "The Private Practitioner's Opportunity and Responsibility in Tuberculosis Case-Finding and Control," by Dr. Robert E. Plunkett, general superintendent of Tuberculosis Hospitals. New York State Department of Health: Hospitals, New York State Department of Health; and "Trends in the Management of Tuberculosis, by Dr. David Cooper, assistant professor of medi-cine, University of Pennsylvania College of Medi-

Discussion of the papers was by Drs. J. Burns Amberson, Jr., visiting physician-in-charge, Tuberculosis Service, Bellevue Hospital, and Herbert R. Edwards, director, Bureau of Tuberculosis, New York City Department of Health.

The American Society of Anesthetists, Inc., announces the election of the following New York physicians as officers for 1944: president, E. A. Rovenstine; secretary, McKinnie L. Phelps; treasurer, Virginia Apgar.

Dr. Howard C. Taylor, Jr., has been appointed chairman of the Department of Obstetrics and Gynecology at the New York University College of Medicine, Dr. Donal Sheehan, acting dean, and

nounced on December 27.

Dr. Taylor has been a member of the faculty of the medical college since 1935. He is associate visiting obstetrician and gynecologist at Bellevue Hospital, attending gynecologist at Roosevelt Hospital, and attending surgeon at Memorial Hospital in New York City. He has written extensively on his specialty and has been directing research on toxemia of pregnancy and kidney func-

A graduate of Sheffield Scientific School, Yale, and the College of Physicians and Surgeons, he is associate editor of the American Journal of Ob-

stetrics and Gynecology.\*

A talk on the prevention and treatment of cancer was given on December 8 to pupils of the James Madison High School in New York City by Dr. Vincent P. Mazzola, under the auspices of the New York City Cancer Committee of the American Society for the Control of Cancer. A question period followed the talk.\*

The county society has indorsed the home nursing course offered women by the American Red Cross.

Dr. J. Stanley Kenney, acting as spokesman for the society, said that the course, offered free and without restrictions as to age, race, or education, represents a valuable contribution to meeting the current medical and nursing shortage.

The shortage, said Dr. Kenney, will continue for some time and may even become worse as wounded service men are brought home. An outbreak of an epidemic disease such as influenza, he pointed out, could be catastrophic unless more women learn

the basic rules of practical home nursing.

Anyone interested in the course may obtain further information from the New York Chapter

American Red Cross, 401 Fifth Avenue.\*

#### Oneida County

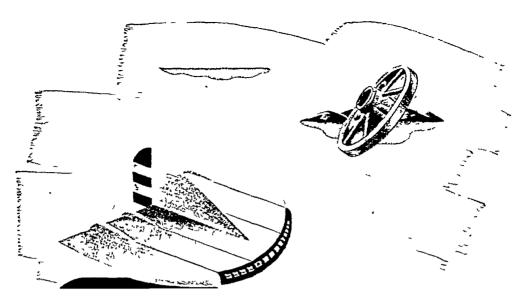

The December dinner meeting of the Utica Academy of Medicine was held at 7:00 r.m. on December 16 in the Hotel Utica.

Dr. Ross D. Helmer, president, reported on the material he has gathered on the proposed Wagner bill now before Congress, which urges socialized medicine. The members discussed the measure.\*

Maj. Mortimer H. Lewis, who has been chief of the eye, ear, nose, and throat division of the Camp Hood Army Station Hospital, Texas, has received his medical discharge and has opened an office here in Utica.

A native of Utica, he was graduated from McGill University. He did postgraduate work in Vienna,

Budapest, and Berlin. For seventeen years he practiced in New York.

The major has been a diplomate in otolaryngology since 1927. He is a member of the New York County Medical Society and the Physicians' Square Club of New York.

#### Onondaga County

The annual dinner meeting of the Onondaga County Medical Society and the Syracuse Academy of Medicine was held at 6:30 P.M. on December 7 at the University Club.

Dr. Louis H. Bauer, speaker of the House of Delegates of the Medical Society of the State of New York and chairman of the Council on Medical Service and Public Relations of the American Medical Association, spoke on "Socialized or Private

Medicine."\*

Dr. Brooks W. McCuen entertained at a dinner on December 2, preceding a lecture at the University of Syracuse College of Medicine by Dr. Clay Ray Murray of New York City. Dr. Murray, who is on the staff of the Presbyterian Hospital in New York and an associate professor at Columbia University, lectured on "Repair of Bone."

The guests were Dr. J. H. Ferguson, Dr. George

Reef, Dr. L. P. Ransom, Dr. Rufus Reed, Dr. Fred Hiss, Dr. Roscoe D. Severance, Charles Ransom, Donald McCuen, Dr. B. A. Stoner, Dr. Har-old Potman, Dean H. G. Weiskotten, Dr. A. G. Swift, Dr. D. S. Childs, Dr. E. W. Kennedy, of Roch-ester, and his son, Robert Kennedy.\*

Dr. Dwight V. Needham and Dr. Carlton F. Potter were elected presidents of the Onondaga County Medical Society and the Syracuse Academy of Medicine, respectively, at the annual joint dinner meeting at the University Club in Syracuse in December.

Dr. Needham succeeds Dr. Herbert C. Yeckel

and Dr. Potter succeeds Dr. J. G. F. Hiss.

Other officers of the county society are Dr. P. K. Menzies, vice-president; Dr. F. N. Marty, secretary, re-elected; Dr. I. L. Ershler, treasurer; Dr. A. N. Curtiss and Dr. Potter, censors; Dr. W. W. Street, delegate to the State Society, and Dr. F. S. Wetherell, alternate; Dr. W. R. Dolan, of Skaneateles, Dr. W. O. Kopel, Dr. J. H. Walsh, Marcellus, and Dr. G. L. Wright, delegate to the Fifth District and Dr. G. L. Wright, delegates to the Fifth District

Other officers of the Syracuse Academy are Dr. G. C. Goewey, vice-president; Dr. M. C. Hatch, secretary; Dr. G. R. Lewis, treasurer, re-elected; Dr. Hiss, Dr. C. D. Post, and Dr. F. R. Webster, council members; Dr. B. W. McCuen, trustee.\*

#### Ontario County

The Canandaigua Medical Society met on December 9 with Dr. D. A. Eiseline, of Shortsville, in the

Canandaigua Hotel.

The members heard a review of Paul de Kruif's book, Kaiser Wakes the Doctors, by Dr. C. Harvey Jewett. The group also discussed the Wagner-Murray bill for extension of the social security plan.

Dinner was served to eleven guests.
Dr. J. Wendell Howard, East Bloomfield, was host for the annual meeting of the society on January 13, when Dr. Margaret T. Ross gave the

president's address and officers were elected. The list of officers will be published in a later issue.

#### Orange County

Two former Port Jervis physicians who have won recognition in New York City were speakers at the 137th annual meeting of the Orange County Medical Society held on December 14.

The two speakers were Dr. Nathan B. Van Etten, a former president of the American Medical Association and a consultant physician at Morrisans Hospital, the Bronx, and the Bronx Eye and Ear Hospital; and Dr. Edward R. Cunnifie, director of surgery at Fordham Hospital, and a trustee of the Medical Society of the State of New York.

Election of officers for 1944 was held and reports of last year's activities and plans for the future

were also features of the program.

The names of the new officers will be published

#### Queens County

At the annual meeting of the county society, held at the Medical Center in Forest Hills on November 30, the following physicians were elected officers for 1944: president, W. Guernsey Frey, Jr., of Forest Hills; president-elect, Edward C. Veprovsky, of Flushing; secretary, Ezra A. Wolfi, of Forest Hills; assistant secretary, Leo Goldberg, of Jamaica; treasurer, Arthur A. Fischl, of Long Island City; assistant treasurer, Lawrence M. Waterhouse, of Jamaica; historian, Joseph S. Thomas, of Flushing, Alberta Libraries, Alberta Alberta Libraries, directing librarian, Alfred Angrist, of Jamaics; assistant directing librarian, Sol Axelrad, of Woodhaven; trustees: Joseph D. Hallinan, of Richmond Hill; Jacob Werne, of Jamaica; Robert R. Yanover, of Flushing; censors: Alfred E. Passera, of Woodside; Arthur G. Whelan, of Jackson Heights; Frank J. Cerniglia, of West Forest Hills; Daniel Porte, of Jamaica; delegates to the State Society: Thomas M. d'Angelo, of Jackson Heights, and Dr. Werner delegates; Godwin A. Distler. Werne, alternate delegates: Goodwin A. Distler, of Woodhaven; Dr. Hallinan, and Dr. Veprovsky.

Dr. Jacob Werne is the retiring president.

Dr. Elizabeth G. Sunners of Sunnyside has 18cently been commissioned an officer in the SPARS with rank of Lieutenant Commander, and will leave shortly for active duty at Long Beach, California, after a two weeks' indoctrination course here. Dr. Sunners, who has been practicing in Queens for many years, is the first woman member of the society to enter any of the branches of the military service.

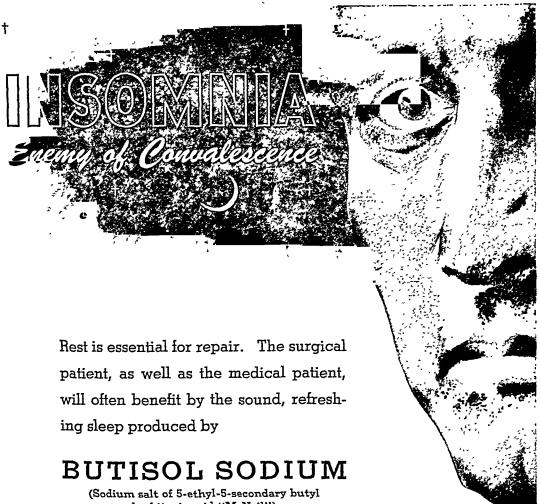

She was graduated from Fordham University with the degree of Ph.D. in 1923 and received her M.D. from the University of Vermont in 1930. She has been a member of the Child Welfare Com-

mittee for the past six years.

For the stated meeting on January 25, 1944, the society will have as its guest speaker Dr. Hugh Young, of Baltimore, professor of urology at Johns Hopkins University and director of Brady Urological Clinic.

Dr. Young is the author of an autobiography which became a national best-seller. He can always be counted upon for an instructive and entertaining discourse. His paper will be on "The

[Continued on page 204]

barbituric acid "McNeil")

Despite its powerful sedative and hypnotic action, Butisol Sodium is less toxic than phenobarbital in comparable effective dosage.

Indications

Insomnia, preoperative sedation, neuroses, obstetrical hypnosis, spasticities, hypertension, postoperative pain

Capsules Butisol Sodium 11/2 gr. Supplied in bottles of 100, 500 and 1000

Trial supply on request.

Medical and Surgical Aspects of Hypertrophy and Cancer of the Prostate," but it is anticipated that Dr. Young will have many interesting things to say on the conduct and social problems of the presentday members of the armed forces of both sexes.

#### Richmond County

Dr. D. V. Catalano, acting president of the Richmond County Medical Society since the death of Dr. H. Lynn Halbert last April, has been elected president of the organization. Dr. Catalano served as vice-president under Dr. Halbert.

Other new officers of the society are Dr. Milton S. Lloyd, of West Brighton, vice-president; Dr. Herman Friedel, of St. George, secretary; and Dr. Curtis J. Becker, of St. George, treasurer.\*

#### Rockland County

The Rockland County Medical Society met on December 15 at the Eureka House, Suffern, and elected officers as follows: president, Dr. Harold S. Heller, of Spring Valley; vice-president, Dr. Edwyn O'Dowd, of Tappan; treasurer, Dr. Marjorie Hopper, of Nyack; secretary, Dr. Robert L. Yeager of Pomona.

Dr. Hopper as trustee succeeds Dr. Dean Milti-more, of Nyack, who has served the society as an officer for twenty-six years but who has voluntarily

retired.\*

Dr. Kurt B. Blatt, of Haverstraw, has been named physician for the Rockland County jail.

Dr. Blatt succeeds Dr. Matthew Dal Lago, of New York City, who resigned.\*

#### Schoharie County

The following news story is clipped from the

Middleburg News of December 9:

The Middleburg Rotary Club honored one of Middleburg's most respected citizens and a member of the local club, Dr. Willard T. Rivenburgh, at its weekly luncheon meeting last Thursday. The occasion marked the eightieth birthday anniversary of Dr. Rivenburgh, who has been a practicing physician in Middleburg for the past fifty-six years and still carries on a very active practice.

James L. Baker, who has known Dr. Rivenburgh since he came to Middleburg in 1887, introduced him as the speaker of the meeting, and paid the physician a glowing and deserved tribute on his long career here. The doctor was the recipient of a birthday cake by the management of Shelmandingly Bertauraby the management of Shelmandingly Bertauraby dine's Restaurant and, in behalf of the club, Dr. Donald Lyon presented him with a basket of flowers.

In his talk to the club, Dr. Rivenburgh related some of his early experiences and numerous humorous incidents. His eightieth anniversary came on Thanksgiving Day, November 25, but inasmuch as no club meeting was held on that day, the event was

put over one week.

Dr. Rivenburgh received his M.D. degree at the University of Buffalo in 1886 and began his practice in the town of Blenheim the same year, residing at the well-known Mel Wright's Hostelry. The followthe well-known Mel Wright's Hostelry. The following year he moved to Middleburg. Three years later, or in 1890, he was married to Miss Belle Stanton, a member of one of the oldest families in this section, and they occupied the house on Clauverwise where they reside at the present time.

With the exception of six months, Dr. Rivenburgh has practiced in Middleburg continuously since

1887. The brief intermission occurred in 19 when he took the civil service examination for position of New York State Medical School spector, and received the highest rating of any cardate. While he enjoyed this new work, he mis his country practice more, so at the end of six mon he resigned his position with the State and cs back here May 15, 1925. Appointed a Schoharie County coroner

Governor Whitman about twenty-eight years a Dr. Rivenburgh has held that office to the pres day, being re-elected each time his term of of ran out. At the November election of this ye he received the largest majority of any candidin Middleburg. Over his long career he has in Middleburg. Over livered over 2,000 babies.

Dr. Rivenburgh is a member of and a Past Mas of Middleburg Lodge No. 663, F. & A. M.; member of the John L. Lewis Chapter, Royal At Masons, Cobleskill; Health Officer of the Villa and Town of Middleburg, and the Towns Fulton, Blenheim, and Gilboa; Physician to t County Alms House; a member and a past-pre dent of the Schoharie County Medical Society a member of the State Medical Society, the Sta School Examiners' Association, and a fellow of ti American Medical Association. He is an activ member of St. Mark's Lutheran Church of Middl burg and holds the office of Elder.

Dr. Rivenburgh was born on a farm in the village of Chatham, Columbia County, and received hearly education in the well-known "little red schohouse," Troy Academy at Troy, New York, an South Berkshire Institute, New Marlboro, Mass chusetts. He served as president of the board ( education of Middleburg, before centralization.

#### Tioga County

The county society held its annual meeting o December 7 at the Green Lantern Inn in Owego Thirty-two members and guests were present.

The guest speaker was Dr. Wallace Hamby

neurosurgeon, of Buffalo. He spoke on "Th Treatment of Low Back Pains."

The annual election of officers was held and re sulted as follows: president, Dr. Hiram L. Knapp of Newark Valley; vice-president, Dr. Harry S Fish, of Sayre, Pennsylvania; secretary-treasurer Dr. Ivan N. Peterson, of Owego; delegates to the meeting of the State Medical Society: Dr. John B Schamel, of Waverly; alternate delegate, Dr. C. S. Johnson, of Spencer; censors, Dr. F. A. Carpente and Dr. F. H. Spencer, of Waverly and Dr. John Laker of Condense. Jakes, of Candor.

#### Tompkins County

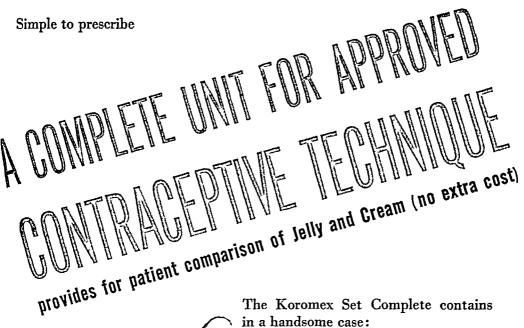

At the annual meeting of the Tompkins County Medical Society held on December 21, 1943, the following officers were elected: president, Dr. Joseph N. Frost; vice-president, Dr. Robert H. Broad; secretary, Dr. Willets Wilson; delegate to the State Society (for two years), Dr. Leo P. Larkin; alternate delegate, Dr. Henry B. Sutton; censors: Dr. Frederick Beck, Dr. Leo P. Larkin, Dr. Hudson J. Wilson, Dr. Charles D. Darling, and Dr. Leo H. Speno. and Dr. Leo H. Speno.

All of the officers are residents of Ithaca.

#### Ulster County

Dr. James J. Britt has opened an office in Kingston to engage in the practice of obstetrics and general medicine.

Dr. Britt is a native of West Hurley, a graduate of Holy Cross College and of Albany Medical

For three years following an internship at Highland Hospital, Rochester, New York, Dr. Britt practiced medicine at Napanoch.

On October 1, 1943, he completed two years' postgraduate work in obstetrics at the A. N. Brady Maternity Home in Albany.

#### Wayne County

The annual meeting of the Wayne County Medical Society was held at the Hotel Wayne in Lyons on December 7. Dinner was served at 6:30 o'clock, after which officers were elected and the yearly reports were given.

Dr. Paul A. Lembeke, of Rochester, district state health officer, gave a talk on "Tropical Diseases." Dr. Lembcke was in Central America during the past summer. The names of the new officers will be published in a later issue.\*

#### Westchester County

Dr. Camillo A. Cerchiara has been appointed chief of the Emergency Medical Service of Mount Vernon's Civilian Protection Organization, to fill the vacancy created by the death of Dr. William T.

Dr. Cerchiara, who has been a member of the Emergency Medical Service since its inception two years ago, has practiced medicine in Mount Vernon for a score of years. He received his B.S. degree in 1918 at City College in New York, and his M.D. degree in 1922 at Cornell University Medical School. He interned in Mount Vernon Hospital from 1922 to January 1, 1924.

Dr. Cerchiara took postgraduate work in ob-

stetrics in 1928 at Lying-In Hospital, New York City, and has been on the medical staff of Mount Vernon Hospital for many years as assistant ob-

A member and former president of the Mount Vernon Medical Society, Dr. Cerchiara also is a member of the Westchester County Medical Society and the American Medical Association.\*

Dr. John A. P. Millet, of New York, chairman of the Emergency Committees of the Neuro-Psychiat-ric Societies of New York City, and director of the Lake George Foundation, spoke on "The Role of Civilian Agencies in the Rehabilitation of Neuro-Psychiatric Casualties" before the Scarsdale Woman's Club on December 15. Dr. Michael M. David, of White Plains, chairman of the Committee on Research and Medical Economics, spoke on "Our Role After Victory in Health and Medicine."\*

#### Wyoming County

One of Wyoming County's oldest practicing physicians rounded out fifty years as a "country doctor" on December 11. He is Dr. Lon E. Stage, 78, of Bliss. Friends throughout the county honored him at a testimonial.

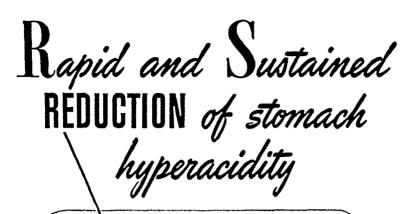

All of Dr. Stage's medical career has been passed in the Wyoming County hamlet of Bliss He went there directly after graduation from the University of Buffalo Medical School in 1893 He was a member of the first class to be graduated from that institution.

Dr. Stage has been away from his ministering but once in his life. "I caught smallpox from a patient, and was really sick," he explains.

Dr. Stage is a native of Elmira.\*

When *Creamalin* is taken, acidity in the stomach is reduced promptly. This is followed by a slow and persistent antacid effect.

With *Creamalin* no secondary rise in secretion of acid gastric juice occurs. Moreover, there is no danger of producing alkalosis.

Creamalin often induces rapid healing of peptic ulcer when employed with an ulcer regimen.

Creamalin Tablets are convenient to carry and easy to take—and they are palatable.

Supplied in bottles of 50 and 200 tablets.

#### OCD and Hospital Association to Recruit Men for Volunteer Hospital Service

O ASSIST in relieving the nation-wide shortage of manpower in hospitals, the U.S. Office of Civilian Defense and the American Hospital Association are jointly sponsoring a plan to recruit men volunteers to perform many of the less skilled tasks. In a joint statement the two agencies point out that business men, laborers, and white-collar workers are already assisting in the care of patients and property, as well as in maintenance work and operation, in hospitals in several communities.

Local defense councils stand ready to assist hospital administrators in publicizing the needs of their hospitals and in recruiting volunteers. The statement, which is addressed to hospitals, announces that the Civilian Defense Volunteer Offices will canvass the sources of supply, appeal to the public through press and radio, and provide speakers to recruit volunteers through men's organiza-

tions.

Health and medical committees of the War Services Board of the local defense council, on which hospitals are represented, may ascertain the extent

of the manpower problem.

It is recommended that hospitals determine what tasks men volunteers can take over, determine how to arrange schedules so that the men can be used, and make arrangements within the hospital for selection, training, organization, and supervision. There should be a director of volunteers, who would be responsible for selecting and scheduling the volunteers. In addition to specific training, special attention should be given to orientation in the traditions, ethics, policies, procedures, and physical layout of the hospital, the statement advises.

A special announcement recently sent to defense councils pointed out that each hospital will wish to work out the details of training to conform to its own organization and procedures.

To stimulate morale and efficiency, it is suggested that the "Hospital Men Volunteers" be designated a special unit of the U.S. Citizens' Service Corps. A standard uniform of a gray coat of three-quarter length, with the insigne of the Citizens Service Corps on the sleeve, is recommended for adoption.

The program to extend volunteer services for men has been worked out by the Medical Division and the War Services Branch of the Office Civilian Defense. OCD has been guided by a committee of the American Hospital Association appointed to advise the War Services Branch on the program. Members of the committee are: Mr. Oliver G. Pratt, superintendent, Salem Hospital, Salem, Massachusetts, chairman; Mr. Ralf Couch, administrator, University sity of Oregon Medical School Hospitals and Clinics, Portland, Oregon; Dr. Robin C. Buerki, dean, Graduate School of Medicine, University of Pennsylvania, and medical director, Hospital of the University versity of Pennsylvania, Philadelphia; Mr. Frederick D. Grave, New Haven, Connecticut, director of men volunteers, New Haven Hospitals, New Haven Conn.; Dr. Jack Masur, Hospital Officer, Medical Division, Office of Civilian Defense, Washington, D.C.; Miss Marian Randall, Chief Nurse, Medical Division, Office of Civilian Defense, Washington, D.C.; Mr. Frank Walter, Denver, Colorado, president, American Hospital Association, ex officio; Dr. George Baehr, Chief Medical Officer, Office of Civilian Defense, Washington, D.C.

#### New Hospital for Peru's Upper Amazon Development

PUCALLPA, terminus of a motor highway across the Andes Mountains into Peru's upper Amazon country, is the site of a new hospital built to aid in the development of the area for production of rubber, quinine, and other economic resources.

The Pucallpa hospital is one of several hospitals, health centers, and dispensaries being established in Peru's trans-Andean territory with the aid of United States doctors and sanitary engineers. These are providing modern health services in the region for the first time in connection with colonization and development plans.

The great trans-Andean highway, opening the way for motor transport across the Andes to link with the Amazon navigation system to form a transcontinental route, recently has been extended

as far as Pucallpa.

A few years ago Pucallpa was a small settlement on the Ucayali River, undistinguished from other jungle settlements in the upper Amazon valley.

Now Pucallpa is the meeting place of the two systems of transportation which make the first transcontinental land-water route across the Amazon

basin from the Pacific to the Atlantic.

The interconnecting waterways of Peru's Amazon valley lead from Pucallpa to Iquitos, Peru's port for ocean-going steamers 2,000 miles up the Amazon river from the Atlantic. The new Central Highway of Peru runs from the port of Callao, on the Pacific

Coast, across Andean ranges and dips into the Amazon valley to Pucallpa.

Opening of a 258-mile stretch of this highway to Pucallpa coincided with the completion of the hospital. Both projects were dedicated on the same day recently by President Prado of Peru, who motored from Lima.

Peru always has envisioned the Central Highway as a key to unlock her Amazonian riches. In this development Pucallpa was to play a large role be-because of its strategic location. These were peace-

time plans.

Now these plans have been adjusted to a wartime The Amazon Valley, including the Perupattern. vian section, is the scene of a rubber development program. One of the biggest problems is transportation of food, drugs, equipment, and other supplies into the rubber country.

Before the extension of the highway, supplies moved into the region of the Ucayali River, as well as other parts of the Peruvian rubber country, mainly from Iquitos. It is a week's trip or more by

rivers to Iquitos.

As terminal of the highway, Pucallpa becomes a natural supply base for the Ucayali River region. It also is a port for collection of rubber for relay overland to the Pacific coast.

Altogether five hospitals and fifteen dispensaries [Continued on page 210]

The potentiation of the central action of phenobarbital by the belladonna alkaloids (Friedberg, Arch. f. exp. P. & P. CLX. 276) renders possible attainment of desired effects with relatively small doses, thus avoiding hang over" and other unpleasant side actions. In contrast to galenical hang over" and other unpleasant side actions. In contrast to galenical preparations of belladonna such as the tincture, Belbarb has always the same proportion of the alkaloids.

Indications: Neuroses, migraine, functional digestive and circulatory disturbances, vomiting of pregnancy, menopausal disturbances, hypertension, etc.

Formula: Each tablet contains 1/4 grain phenobarbital and the three chief phenobarbital and the three chalkaloids, equivalent approximately 9 minims of tincture of belladonna.

Belbarb No. 2 has the same alkaloidal content but 1/2 grain phenobarbital per tablet.

CHARLES C. HASKELL & CO., INC., RICHMOND, VIRGINIA

#### SHOES AS THERAPEUTIC AGENTS

No doctor can ignore that shoe therapy is a major factor in the treatment of many foot disorders. In some cases, however, when further medical or surgical treatment is required, the shoes must be adjusted to conform to any changes such treatments make in the shape or size of the feet.

Pediforme shoes are prepared through experienced craftsmen to make the necessary adjustments as prescribed by the orthopedic surgeon or physician in these cases.

With purchases restricted it is readily apparent that substantial shoes, capable of reconstruction or easy adjustment, should be prescribed. For all practical purposes, Pediforme footwear may well be considered in shoe therapy.

are to be built at convenient points. Pucallpa has the first completed hospital. It is fitted with 32 beds, a laboratory, and water supply and power

A hospital nearing completion at Iquitos-headquarters of Peru's rubber production program—will house 80 patients and will be equipped with laboratory and x-ray apparatus .- Release from the Office of the Coordinator of Inter-American Affairs.

#### Walsh Outlines Veterans' Need for More Hospitals

PRESENT and future of Veterans Facilities and I the need for many more hospitals for the hospitalization of service men of the first and second World Wars and the Spanish-American War, each veteran of which is entitled to it, were outlined to the Saratoga Historical Society by Dr. John S. Walsh, physician-in-charge of the Veterans Facility at the Spa, at a meeting held in November, at which Former Supreme Court Justice Irving I. Goldsmith, a vice-president of the institution, was host at his home.

Some ten millions, Dr. Walsh said, are entitled to hospitalization, and he drew a picture of need to be prepared for vocational rehabilitation of the veterans who are being discharged at the present

rate of 35,000 a month.

The problem of re-employment for the returning veterans now trickling back and soon to come in a rush deserves the careful consideration of everyone, Dr. Walsh felt. At present, there are some 85,000 beds in ninety government hospitals and it is not nearly enough, the physician said.

Every veteran whose disabilities are service-connected, he stressed, is entitled to vocational training to fit him for some employment, and his case will be carefully considered by a Board of Vocational training which will guide him into some vocation at which it will be possible for him to work.

In the last war, Dr. Walsh said, some 128,000 veterans took advantage of this vocational education opportunity, and he felt that this plan for veterans of the present war would take care of the em-

ployment of a certain large percentage of the returning veterans.

Growing importance of hydrotherapy treatment for veterans was forecast by Dr. Walsh.

#### 300,000 Beds Needed for Veterans of Second World War

SOME 300,000 beds will be needed to enable veterans of this war to receive hospital and domiciliary care to the extent provided veterans of other wars, according to a statement released to *The Modern Hospital* on November 14, 1943, by Brig. Gen. Frank T. Hines, administrator of Veterans' Affairs.

This estimated maximum, however, should not be required until long after the war. It will necessitate the eventual additional construction of not more than 100,000 beds, because, as General Hines pointed out, under present plans there will be 100,000 beds in Veterans Administration facilities, and it should be possible to obtain at least that many more beds from the Army and Navy shortly after the war terminates when these agencies have completed their medical and surgical treatment of the wounded.

Some 15,000,000 veterans will have the right after

the war to be hospitalized by the Veterans Administration when beds are available, declared General Hines.

At the present time, the Veterans Administration has 66,305 hospital beds in its ninety-three facilities and is utilizing 2,859 beds in other government and contract hospitals. This number will be increased to approximately 87,000 under presently approved or contemplated construction programs. In addition, the Veterans Administration had space for 17,464 beds for domiciliary care, of which 9,466 were oc-

cupied on November 4.

From December 7, 1941, to September 30, 1943, a total of 26,000 veterans of the present war had been hospitalized by the Veterans Administration. that number 7,800 remained under care on September 30, with more than 17,000 having been discharged as recovered, improved, or arrested.—Eva Adams Cross, in the Modern Hospital.

#### Improvements

new emergency and ward admissions department was opened for inspection by St. Luke's Hospital, New York City, late in October. The new unit, which occupies the ground floor of the Norrie Building, is designed to provide modern, centralized facilities for the admission of ward pa-tients and the care of emergency cases. Funds for the modernization project were provided by gifts and legacies and, because of its importance to civilian safety and protection, the War Production Board granted the hospital's application for priorities on building materials.

An 86-bed increase in Syracuse hospital facilities may be expected as a result of grants approved by Regional Director John M. Gallagher of the Federal Works Agency.

Plans for a two-story and basement addition to Lyman wing of the New Syracuse General Hospital will provide dormitory and classroom facilities for student nurses, and will release the fourth floor for an additional 30 hospital beds. The building will cost an estimated \$174,000, of which \$149,000 is provided by the FWA grant.

Plans for a 56-bed addition to Syracuse Memorial Hospital have also been approved by the FWA.\*

Miss Rose Q. Strait, administrator of the Saratoga Hospital, has announced that Annex 1, closed since late in the summer because of shortage of nursing personnel, necessitating consolidation, had been reopened early in December, thus adding 12 beds to the capacity of the hospital.\*

St. Joseph's Maternity Hospital in Troy has a new delivery and obstetric table, bought with the hospital's allotment of the Allied Communities War Chest fund.

\* Asterisk indicates that item is from a local newspaper.

#### At the Helm

H. Chester Larrabee, superintendent of maintenance at City Hospital in Binghamton for nearly fifteen years, has been appointed executive secretary of the Board of Managers of the Broome County Tuberculosis Hospital.

The appointment was made by Dr. A. J. Roach, superintendent, and became effective December 16. Rana S. Cooper, president of the board, announced the designation after a meeting of the

managers with Dr. Roach and Country Attorney Charles P. O'Brien.

Dr. Roach will continue to direct all medical activities at the hospital but Mr. Cooper said that Mr. Larrabee-who resigned from the Hospital Board of Managers in a letter yesterday to the Broome County Board of Supervisors—"will supervise all activities except the medical treatment of patients."\*

John S. Parke has been elected vice-president of the Columbia-Presbyterian Medical Center in New York City. He will succeed John F. Bush, who was named assistant to the president of the board of managers of the institution. Mr. Parke has par-

ticipated in the construction work of every building of the hospital center.\*

Dr. Lyman I. Thayer, superintendent of Westmount Sanatorium, Warren County, has been named by Governor Thomas E. Dewey as a member of the Board of Visitors of the State Hospital for the Treatment of Incipient Pulmonary Tuberculosis at Ray Brook.

He fills the unexpired term of Dr. Thomas H. Cunningham, formerly of Glens Falls, who resigned recently. Dr. Thayer's term will run until

1949.

Prior to 1929, when Dr. Thayer became superintendent of Westmount, he was a member of the staff of the tuberculosis division of the State Department of Health, which position he held eight years. He was born at Newark, N.J., July 28, 1893, and was graduated from the Tennessee Military Institute, Colby College, and the College of Physicians and Surgeons of Columbia University. His internship was served in Albany Hospital.

Dr. Thayer is a member of the Warren Country Medical Society, the State Medical Society, a fellow of the American Medical Association, a member of the Trudeau Society, and a Fellow of the American

College of Chest Physicians.\*

#### Newsy Notes

Fifty-two-year-old Sydenham Hospital, a voluntary institution in New York City's Harlem, will become the first interracial hospital in the city, with a staff of Negro and white physicians and with a white and Negro board of trustees, it has been announced by Joseph Martinson, president.

The interracial board of trustees has already been created by the addition of six Negro members, and the selection of Negro physicians and technicians

will soon follow.

One of the first actions expected to be taken by the expanded board will be to admit Negroes as private patients. Heretofore about 9 per cent of the free patients have been Negro, as well as a substantial proportion of the semiprivate ones. Private patients have all been whites. The hospital has had Negro nurses on its staff for more than six months.
"This hospital is being so organized," Mr. Martin-

son said, "to provide qualified Negro physicians, through staff positions, with opportunities to hospitalize and care for their own patients and to im-

prove their own medical competency.

The hospital is an eleven-story fireproof structure with facilities for clinical and research services. It has 181 beds and 30 bassinets. It is approved by

the American College of Surgeons.

The institution is a full voluntary hospital participating with eighty-six other voluntary institu-tions in the Greater New York Fund, United Hospital fund, and support by the city, and has tax-

exemption privileges.

The interracial plan is the third major innovation pioneered by Sydenham Hospital. Its present building was the first to introduce wiring for telephone and radio connections in every room. 1934, according to a newspaper account at that time, it made a "radical departure from the usual American hospital practice" by offering three weeks' care, valued at \$100, for a premium of \$10 a year, thus bringing hospital insurance to white-collar workers earning less than \$5,000 annually.

The former board of Sydenham will continue to serve. It includes Mr. Martinson; Michael J. Merkin, first vice-president; Edwin C. Boas, second vice-president; Benjamin H. Roth, secretary and treasurer; Sidney Cross, Leon Jarcho, Harold Price, Saul E. Lorberbaum, Leo Cohen, Ralph Engel, and Mrs. Leon Schinasi.

Twelve new members elected to the board are A. A. Astin, William T. Baldwin, Alan L. Dingle, Stephen P. Duggan, Jr., Rev. James H. Robinson, Ferdinand C. Smith, George W. Harris, Mrs. Harriet Shad Butcher, Harry C. Oppenheimer, Mrs. William S. Paley, Frank M. Totten, and Dr. William H. Kilpatrick.—New York Herald Tribune.

November 28 marked the twenty-fifth anniversary of the St. Francis Hospital School of Nursing

in Poughkeepsie.

The school has a student body of fifty young women, forty-eight of whom are members of the United States Nurse Cadet corps, and in February, to assist in training of nurses now so badly needed, the school will take a second entering class, which never before has been done.\*

The White Plains Hospital was one of the principal legatees in the will of the late Clarion B. Winslow.

At 7 P.M. on November 17, 1943, at the Roger Smith Hotel a dinner, celebrating the golden anni-versary of the White Plains Hospital, was held. About 175 attended. Dr. James F. D'Wolf was chairman.

Guests included Dr. and Mrs. Alan Gregg, of Scarsdale, Dr. and Mrs. Guthe, the Rev. William C. Baxter, president of the White Plains Ministers' Asso-

#### MARINOL

(IMPROVED FORMULA)

MARINOL (IMPROVED FORMULA) is an homogenized emulsion of cod liver oil and vegetable oils fortified with fish liver oils of high vitamin A potency to which has been added pure vitamin D<sub>3</sub>.

#### -OUTSTANDING PROPERTIES -

PALATABILITY: The desirable properties of the fish liver oils have been retained without the disagreeable taste and odor.

HOMOGENIZATION: This assures a uniform and stable product that permits of easy miscibility with milk, special formulae, fruit or vegetable juices, or with water.

HIGH VITAMIN POTENCY: 5,000 U.S.P. units of vitamin A and 500 U.S.P. units of vitamin D<sub>3</sub> supply the daily

minimum requirements (FDA) in one teaspoonful.

LOW COST: A single teaspoonful daily is a prophylactic dose.

FOOD VALUE: Fish liver and vegetable oils supply another desirable property—that of caloric value.

EASY ADMINISTRATION is possible because of unusual potency of small dose.

CONSUMER PRICE: Bottle of 6 fl. oz. 85 cents. Bottle of 12 fl. oz. \$1.50 (M.P.R. 392). HOW SUPPLIED: Bottles of 6 fl. oz. and 12 fl. oz.

Worcester Massachusetts [Continued from page 212]

ciation, Miss Grace Roberts, first graduate of the School of Nursing, Mrs. Alan Chalmers, of Scarsdale, chairman of the Nursing School committee, and Miss Winifred Smith, school director.

Alexander C. Nagle, of Scarsdale, board president, presided. Dr. Gregg, medical education director of the Rockefeller Foundation, spoke on "Medicine 50 Years Hence." The High School A Cappella Choir sang.

An open house was held at the hospital on

November 21 from 3:00 P.M. to 6:00 P.M.

Dr. Thorstein Guthe, Deputy Surgeon-General of the Royal Norwegian Government-in-Exile, spoke at 1:30 P.M. on November 17 over Radio Station WFAS on "Norway at War." He mentioned care of Norwegian seamen at White Plains Hospital.

At the annual meeting of the Dansville General Hospital Corporation the following directors were elected for periods of three years: Dr. Harold Hulbert, Dr. Simon King, Frank McTarnaghan, Thomas M. Bowes, Fred F. Biek, Gamble Wilson, Miss Helen Pratt, Mrs. Elizabeth Scherer, and Mrs. Floyd Shepard.\*

Patients at the Batavia Hospital will be provided with books to read through the cooperation of the Twigs, a group of high school girls who are actively connected with the hospital. A book shelf is being planned which will be wheeled around the rooms two or three times a week, so that patients may select books.\*

The establishment of an award for house officers of the Rochester General Hospital, Rochester, to be known as the Harry D. Clough Memorial Prize, was announced on October 22, 1943. The award,

which will consist of a \$25 cash prize, will be granted at the close of each weekly conference session to the house officer who has contributed most to the success of the conferences in the quality of case presentations, discussion, and assistance in the selection of clinical material. The name of the winner will be placed on a special plaque which has been hung on the north wall of the conference room. The judging committee will be formed from staff members. The creation of the prize will be a fitting memorial to Dr. Clough, assistant medical director of the hospital, who died October 1, 1942, and who worked for the development and improvement of the hospital conferences.

Dr. John L. Norris, of Rochester, addressed the Practical Nurses of New York, Inc., Western Division, at their monthly meeting on December 7 at 8 p.M. in the Nurses' Home of the Monroe County Hospital. His subject was "The New Medicines, and What the Doctor Expects the Practical Nurses to Know About Them."\*

The sum of \$180,000 to prepare plans and specifications for a new general hospital for Queens County after the war was approved by the Board of Estimate on December 2, at which time it was disclosed that a site in Elmhurst is to be selected for it.\*

Two ambulances were presented to the Army on December 5 by the Federation of Slovak Societies of Greater New York at a ceremony in St. John Nepomucene's Roman Catholic Church.

Nepomucene's Roman Catholic Church.
The speakers hailed the patriotism of the Slovak-

Americans.

Representative Martin J. Kennedy and State Senator James Donovan were among the speakers. Lieut. Dorothy Bennett, a WAC, accepted the ambulances in the name of Maj. Gen. Thomas A. Terry of the Second Service Command.\*

#### REVIEWED

Air-Borne Infection. Some Observations on Its Decline. By Dwight O'Hara, M.D. Octavo of 114 pages, illustrated. New York, Commonwealth fund, 1943. Cloth, \$1.50.

Dr. O'Hara has brought together, within a small volume, a group of brief essays upon some of those diseases which gain entrance into the body by way of the respiratory tract. As professor of preventive medicine at Tufts College Medical School and as a well-known Boston clinician, he has analyzed the past and present importance of these infections. He offers a prediction that they will ultimately be brought under control, just as the enteric infections have already been relegated to a place of minor significance.

In view of the well-established evidence of airborne transmission of infection presented by Wells, Trillat, Cruikshank, Allison, and others, medicine may anticipate more effective specific means for the prevention of these diseases, and yet Dr. O'Hara wisely emphasizes that other factors are already operative toward accomplishment of this goal.

THOMAS D. DUBLIN

Flying Men and Medicine: The Effects of Flying upon the Human Body. By E. Osmun Barr, M.D. Octavo of 254 pages. New York, Funk & Wagnalls Co., 1943. Cloth, \$2.50.

Dr. Barr was an officer in the Air Corps of the United States Army in the first World War, and received his medical degree in 1924. He is following aviation now as a flying doctor. He knows his aviation.

His book is designed to familiarize flyers with the anatomic and physiologic reasons for strict and repeated examinations to insure adequate physical fitness. Inasmuch as the text is addressed to laymen, the doctor speaks in plain language, with explanations of scientific terms when necessary. The lay reader can read the book with interest and profit, and the discussions will be instructive to those doctors concerned in this specialized branch of medicine.

Joseph Raphael

The Principles and Practice of Industrial Medicine. Edited by Fred J. Wampler, M.D. Octavo of 579 pages, illustrated. Baltimore, Williams & Wilkins Co., 1943. Cloth, \$6.00.

The problems of industrial medicine today confront the general practitioner as well as the specialist. Many practitioners must assist the small number of physicians in industrial medicine in conserving the

health of the war workers.

Thirty-three experts in their respective fields have contributed to make this volume one of the most interesting and practical books on the subject to have appeared within recent years. The contribu-tors include medical directors of large industrial plants, physicians in public health service, research workers in physiology, sanitary engineers, and teachers of preventive and industrial medicine. The work is up to date and there is firsthand information on every subject.

There are chapters on industrial accidents, the effects of temperature and humidity, abnormal atmospheric pressures, control of exposure to toxic chemicals, poisoning by metals and gases, effects of electricity, occupational diseases of the skin, eye injuries; there are chapters on industrial medical services for smaller plants, and other chapters on industrial health with which the general practitioner as well as the specialist should be familiar. Although a discussion of surgery is omitted, the treatise is comprehensive and includes chapters on traumatic shock, burns, and vocational and industrial rehabilitation. This textbook should prove useful for undergraduate students and graduates in medicine interested in the many phases of industrial health and industrial medicine.

The editor and individual contributors are to be

congratulated upon this excellent work.

IRVING GRAY

Hospital Discharge Study. By Neva R. Deardorff and Marta Fraenkel, M.D. Vol. 2, Hospitalized Illness in New York City. Octavo of 349 pages, illustrated. New York, Welfare Council of New York City, 1943.

This is a report on hospitalized illness in New York City, and is the second of the three volume publication, Hospital Discharge Study, a project of the Welfare Council of New York City.

This particular volume is arranged according to diagnoses of over one-half million patients dis-charged from 113 hospitals in New York City in 1933. It includes analyses of data on patients with tumors, obstetric conditions, surgical and traumatic conditions, acute communicable diseases, tuberculosis, venereal diseases, diabetes, arthritis, and several other diseases.

The study is obviously of special interest to administrators and medical staffs of hospitals. it should be valuable also to those physicians who know how to use such data as the basis for a more intelligent approach to the medical problems of the

communities in which they practice.

ALFRED E. SHIPLEY

Synopsis of Tropical Medicine. By Sir Philip Manson-Bahr, M.D. Duodecimo of 224 pages, illustrated. Baltimore, Williams & Wilkins Co. 1943. Cloth, \$2.50.

This small book dealing with tropical medicine is thorough, though in synopsis form. It deals with the cause, clinical course, and treatment of tropical

diseases. It is a practical work, well worth while for a quick review. It includes many conditions of general interest other than just tropical afflictions; for instance, animal poisons such as snake bite and spider bite, as well as disturbances due to climatic conditions, heat exhaustion, sun traumatism, etc. recommend it highly for its value, particularly at this time.

EUGENE R. MARZULLO

## Crifles make perfection, and perfection is no trifle!

Michelargelo

This was the creed of Niichelangelo Trifles—menial tasks and lesser elements of precision—always mented his most careful personal attention in his constant aim for perfection.

Similarly, the pharmaceutical chemist has exercised meticulous care and scientific precision in the complex manufacture of the organic iron preparation. Arsenoferratose Elixir Skillful blending of selected ingredients and diligent attention to numerous so-called "trifles" have contributed to produce its superb palatability and perennial efficiency Indeed, in the minds of many physicians. Arsenoferratose Elixir is "the iron tonic of perfection" for all those anemias known to be benefited by iron therapy

Supply: Arsenoferratose Elixir, Arsenoferratose Elixir with Copper, and Ferratose Elixir, are supplied in bottles of 8 fluid ounces

Dosage. 1 to 3 teaspoonfuls, 2 or 3 times daily, according to age and requirements.

[Continued from page 216]

Geriatric Medicine. Diagnosis and Management of Disease in the Aging and in the Aged. Edited by Edward J. Stieglitz, M.D. Octavo of 887 pages, illustrated. Philadelphia, W. B. Saunders Co., 1943. Cloth, \$10.

This volume is the work of many well-known writers, each covering his particular field. Geniatrics is stated by the editor to be not a specialty but rather an attitude of mind which takes notice of the changes which result from aging.
Its objective is "to add breadth and depth rather

than mere length to life."

Many of the articles are quite comprehensive and present an excellent description of the diseases of old age, which makes this one of the best volumes on the subjects treated.

W. E. McCollon

What to Do Till the Doctor Comes. By Donald B. Armstrong, M.D. Sextodecimo of 354 pages, illustrated. New York, Simon & Schuster, Inc., 1943. Cloth, \$1.00.

What to Do Till the Doctor Comes supplies an amazing quantity of valuable information for the layman. As stated by the authors, it is "designed to be the partner of the family medicine chest" and it could well serve as an excellent guide for what goes into such a chest. Prepared by a distinguished medical authority on health and safety and published in a convenient, readable, quick reference form, this small volume fills an urgent need. A physician who recommends this booklet to his patients will reap dividends both in his own valuable time and in their welfare and comfort.

THOMAS D. DUBLIN

The Microscope and Its Use. By Frank J. Muñoz in collaboration with Dr. Harry A. Charipper. Octavo of 334 pages, illustrated. Brooklyn Chemical Publishing Co., Inc., 1943. Cloth, \$2.50.

This book is a highly practical treatise on the microscope, written in nontechnical language with a minimum of mathematics and "optics." The text a minimum of mathematics and "optics." The text is full of helpful hints and many "don'ts" to guard the reader against common mistakes. The numerous fine illustrations and diagrams, the excellent index, bibliography, and glossary add greatly to the value of the book.

Especially noteworthy are the chapters on the condenser, that so often misunderstood part of the microscope, on microscope illumination, and on the binocular microscope. Other chapters are devoted to stereoscopic, metallurgic, and polarizing microscopes, and to the microtome.

ARNOLD H. EGGERTH

Pictorial Handbook of Fracture Treatment. By Edward L. Compere, M.D., and Sam W. Banks, M.D. Octavo of 351 pages, illustrated. Chicago, Year Book Publishers, Inc., 1943. Cloth, S4.25.

Compere and Banks have graphically simplified the application of the principles and treatment of fractures in their Pictorial Handbook of Fracture Treatment. They have chosen to illustrate only the more readily acceptable methods of treatment. The lew selected x-rays and the excellent drawings will make this an extremely valuable reference book for the student and surgeon who now must manifest an interest in these injuries. In no recent book has so much been so briefly yet so adequately covered. The various fractures are presented in such a simple and yet complete form as to make the work of inestimable value.

#### MEDICINE IN THE NEWS

James B. Reston, in the New York Times, mentioning Winston Churchill's illness, stated, "The weakness of greatness is that it is irreplaceable."

Which gives birth to a thought that perhaps in the not-to-distant future, some doctors may well argue that it was the medical profession that actually shortened this war by restoring Churchill back to health quickly.

The bubble that penicillin can be grown at home at an initial outlay of less than five dollars and a production cost of 5 cents a dishful, has been burst by the report of a producer of this new drug who has invested \$1,500,000 in the manufacture of it. According to the facts, it is extremely difficult to prevent infection of the mold by foreign organisms during fermentation. Even slight infection will completely destroy the penicillin and possibly result in the formation of toxic products. Besides that little problem, the extraction of penicillin from the fermentation liquor free of harmful impurities is most exacting. So it is no homemade remedy.

#### LIFE IN THE HIGHER PLANES

The effect of high altitudes on the human body is a study that the war has made necessary. At Northwestern's Medical school the x-ray is being used for such studies. Films have been taken of

men theoretically flying at altitudes of seven miles.

These films showed marked and significant changes in the heart, lungs, joints and muscles of volunteer pilots. It has long been known that at 38,000 feet, many pilots experience pain caused by strenging of mace within different parts of the expansion of gases within different parts of the body. The gases in certain body fluids have normal channels for expansion. However, particles of dissolved gases which lodge in fat tissue and the joints will expand when outside pressure decreases. The pain caused by this expansion, according to some of the test cases, is more severe than in rheumatism.

Occasionally gas in a flier's stomach at 38,000 feet will expand about six times. Bubbles and airpockets on the films appeared large in many cases. One picture taken at the theoretical 38,000 feet revealed a large air-pocket beneath a knee joint. It was not there before or after the test.

What caused the pocket and why did it disappear? Physiologists are now seeking the answer to that question.

#### THE LINE IN TRAVEL

Where to draw a line between essential and nonessential travel is still a matter to be left up to the judgment of the individual and to his or her own patriotic honor.

The vacation resorts, in spite of a campaign to make the public less travel-minded during this war, have never enjoyed such a tremendous business. During the past year hotel rooms have been as scarce as steaks, and have required almost as much "know-who" as "know-how" to obtain. The railroads, with all their implorings to stay at home unless it was a matter of life or death, are still confronted with a problem of transporting twice the number of passengers with less unassigned rolling stock available and less train crews to man the cars.

The travel business, meaning all the men and women who must continue to earn a living through reservations and bookings, are practically out on a limb trying to maintain some form of neutrality—torn between a "must" to discourage unnecessary travel and a "must" to serve clients who insist on going places to get away from it all.

In the vastly reduced travel and resort advertising, the trend is toward "health" vacationing. Even though an evident subterfuge, it seems the only recommendation left the hotels and resorts for enticing clients or logical reason for advertising and keeping their names in the minds of the public.

But travel, people still must or will regardless of hardships or inconveniences. Florida is again host to thousands who wish to escape the rigors of a northern winter, while the northern resorts are being stormed by the red-blooded who prefer the snow and ice for healthy recreation.

Locally and within decent travelling distance, the Berkshires, the Timber Trail section and Lake Placid in the Adirondacks, Salisbury in Connecticut, and the Poconos all provide excellent winter sports. On the list of even closer resorts are Phoenicia with new ski trails, and North Creek.

These places are not just for the active sportsman; many vacationists go for the fun of sleigh rides, dogteam jaunts, skating or merely loafing in front of a glowing fireplace in a pine-scented lodge.

#### RETROSPECTION

Along with some hardships (at least hardships for Americans) the war years have brought the highest rate of production and earnings in history.

The solution to unemployment was finally brought about by the demand for manpower in our fighting forces. Millions of jobs have been created and filled by women who had been on no payrolls. The expenditure of over \$150,000,000,000 on war materials alone trebled the manufacturing payroll and doubled the national income. The result—many Americans, especially in the lower income brackets have the greatest purchasing power they have ever had.

A comparison with peacetimes shows that 27 million (or 71%) more employees are now at work than in 1933, the permanently unemployed list of 12,750,000 in that year has been completely wiped out, and it is estimated that our 65,000,000 employed in 1943 have helped to build up a national income of 155 billion dollars.

The national income is almost twice that of 1929

(our last peacetime boom year), almost four times that of 1933 (the low ebb of depression), and almost three times that of 1939.

But looking ahead, we face the problem of returning some 11,000,000 soldiers and sailors to job when peace comes and the problem of what to do with the 20,000,000 persons now in war work. Eliminating the number of women who will return to housework and the number of men who may be retained in the armed services, economists still see a need for at least 10,000,000 to 15,000,000 new jobs to support the buying power upon which post-war prosperity will naturally depend. Higher prosperity levels, to offset possibly rising taxes, would require even more jobs or an incentive for production as strong as the current war work.

To partly offset the strain of such a vast reconversion, plans now are aimed at tapering off war contracts as production goals are met and to gradually switch industry back to peace production.

#### for NEPHROPTOSIS

TOGETHER with treatment for any existing infection of the urinary tract, Camp Supports have proven valuable adjuncts in the relief of symptoms in many cases

Camp-trained fitters have been instructed to consult the physician as to the position required for the fitting, if reclining or partial Trendelenburg. In the event that the physician desires the use of a pad, the fitter has been instructed to obtain information as to the type of pad to be used and to ask the doctor to mark on the garment or blue pencil upon the patient the exact location of the pad.

#### Advantages of Camp Supports in Conditions of Nephroptosis:

- 1. The "lifting" power of Camp Supports is from below upward and backward.
- **2.** Camp Supports are an aid in improving the faulty posture that sometimes accompanies renal mobility.
- 3. Camp Supports are easily and quickly adiusted.
- 4. Camp Supports stay down on the body by reason of the foundation laid about the pelvis.
- 5. Camp Supports are comfortable.
- 6. Camp Supports are economically priced

Camp fitters ask patients to return to their physicians for approval of the fitting.

is a dependable and effective means of restoring normal tone and activity. INDICATIONS: Syntropan 'Roche' is indicated in pylorospasm, cardiospasm, intestinal colic, spastic constipation, gastric spasm, spasms due to peptic ulcer, megacolon, and tenesmus. DOSAGE: One tablet (50 mg) three or four times a day, or as required. By subcutaneous or intramuscular injection, one ampul t. i. d., or as required. HOFFMANN-LA ROCHE, INC., NUTLEY, NEW JERSEY

\*Phosphate of dl tropic acid ester of 3-diethylamino-2, 2-dimethyl-1-propanol.

#### Iron-Vitamins-Liver

#### for the Rigors of Winter

#### VI-FERRIN

[Dried Ferrous Sulfate, Vitamin B Factors and Liters]

#### Lederle

THE STORMS OF WINTER in northern climates can be withstood only by bodies in physiological balance. Three of the fundamental physiological substances essential to normal health are iron, the B complex vitamins and water-soluble elements of liver.

"VI-FERRIN Lederle" is particularly indicated in the following circumstances —

Hypochromic anemia of pregnancy

Nutritional anemia

Idiopathic hypochromic anomia

Miscellaneous secondary anemias

Hookworm anemia (following removal of the eliology)

The potentiation of the central action of phenobarbital by the belladonna alkaloids (Friedberg, Arch. f. exp. P & P. CLX, 276) renders possible attainment of desired effects with relatively small doses, thus avoiding 'hang over' and other unpleasant side-actions. In contrast to galenical preparations of belladonna, such as the tincture, Belbarb has always the same proportion of the alkaloids.

Indications: Neuroses, migraine, functional digestive and circulatory disturbances, vomiting of pregnancy, menopausal disturbances, hypertension, etc.

Formula: Each tablet contains 1/4 grain phenobarbital and the three chief alkaloids, equivalent approximately to 9 minims of tincture of belladonna.

Belburb No. 2 has the same alkatoidal content but 1/2 grain phenobarbital per tablet.

CHARLES' C. HASKELL & CO., INC., RICHMOND, VIRGINIA

# 

ORETON provides potent, specific replacement therapy for male sex hormone deficiencies, and is indicated in the male climacteric, hypogonadism and prostatic hypertrophy.

ORETON has also achieved impressive results in female disorders such as functional meno-metrorrhagia, intractable cases of functional dysmenorrhea and postpartum breast engorgement.

ORETON-M (methyl testosterone) tablets by mouth; and ointment for inunction.

ORETON (testosterone propionate) in sterile oil solution for intramuscular injection.

Remember too—Prices of ORETON-M Tablets are now about 40% less and ORETON Ampules about 10% less.

# Inture fertility s not impaired

• The essence of planned parenthood is that temporary contraceptive measures will not interfere in any way with future fertility.

The jelly and cream methods generally are considered by authorities to have no influence upon fertility subsequent to discontinuance of use, and there are among our own experimental clinic series sufficient instances of successful planned pregnancy following Ortho-Gynol Vaginal Jelly contraception to substantiate this belief.

The conscientious physician may be assured that future fertility is not impaired by the use of Ortho-Gynol Vaginal Jelly.

Copyright 1944, Ortho Products, Inc., Linden, N.J.

## ortho=gynol VAGINAL JELLY

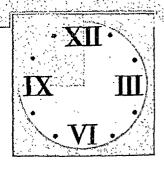

ACTIVE INGREDIENTS: Ricinoleic Acid, Boric Acid, Oxyquinoline Sulfate,

## Paredrine-Su

### Provides all three.

- Prolongal Bacteriostais
- 2 Kon-Simulating Vasoemstietoi
- 3 Theaperrelly West of

(1) Prolonged bacteriostasis. Paredrine-Sulfathiazole Suspension is not a solution, but a suspension of 'Micraform' crystals of free sulfathiazole.

These crystals are not quickly washed away, but form an even frosting over the nasal mucosa. This

fine frosting remains on those areas where ciliary action is impaired by infection—and thus provides *prolonged bacteriostasis* precisely where it is needed most. (The Suspension does not impair normal ciliary action or interfere with drainage.)

#### (2) Non-stimulating vasoconstriction.

While 'Paredrine' exerts a shrinking action more rapid, complete and prolonged than that of ephedrine in equal concentration, it does not produce ephedrine-like central nervous side effects, such as nervousness, restlessness and insomnia.

(3) Therapeutically ideal pH-5.5 to 6.5. No irritation, no stinging and no hyperemia are caused by Paredrine-Sulfathiazole Suspension. Its slightly acid pH range—unlike that of the highly alkaline solutions of sodium sulfathiazole—is identical with that of normal nasal secretions.

This correct pH hastens-

- (1) Restoration of normal ciliary action, and of the germicidal qualities of the nasal secretions.
- (2) Return of the nasal mucosa from a pathologic status of alkalinity to a normal status of slight acidity.

Smith, Kline & French Laboratories, Philadelphia.

# In Peptic Ulcer... Hyperacidity... Gastritis...

## Magmasil

Greater Acid Neutralizing Power

Longer Protective Action

Fewer Doses Needed

No Constipation

Magmasil is available through all pharmacies in 12 oz. bottles.

A stable aqueous suspension of hydrated magnesium trisilicate in extremely fine subdivision, Magmasil is an outstanding advancement in the treatment of peptic ulcer, gastritis, hyperchlorhydria.

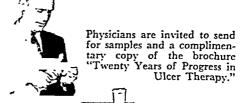

Its antacid action is powerful; one teaspoonful neutralizes 86 cc. of N/10 HCl. It is prolonged, extending over fully four hours.

Hence fewer doses are needed, the customary 11 P.M. administration usually holding the patient comfortable through the night.

Magmasil is free from the drawbacks and limitations of many other antacids. There is no alkalosis, no chloride depletion, no undesirable astringency, no constipation which has made the patient uncooperative with other methods.

Pain and pyrosis are stopped promptly, and healing is brought about rapidly.

GENITO-URINARY
INFECTIONS \_\_

# SULFADIAZINE

Interest in sulfadiazine for the treatment of genito-urinary infections is growing apace. The most commonly encountered uses are—

### INDICATIONS

#### GONORRHEA

A number of investigators have reported the superiority of sulfadiazine to sulfathiazole and other sulfonamides in the treatment of gonorrhea. The report of the Committee on Research of the American Neisserian Medical Society recently stated that although less data for sulfadiazine are available, it appears to surpass sulfathiazole in therapeutic efficiency while manifesting about the same toxicity.

#### OTHER GENITO-URINARY INFECTIONS

Where the invading organisms in the genito-urinary tract are found to be E. coli, A. aerogenes, Shigella dispar, hemolytic streptococci or staphylococci, sulfadiazine by mouth is indicated. Sulfonamides are relatively ineffective against Streptococcus faecalis.

#### ADMINISTRATION

#### GONORRHEA

For acute gonococcal urethritis in the male, a dosage of 2 Gm. daily for from 4 to 8 days has been recommended. Alternatively, a dose of 4 Gm. daily, in divided doses for 5 days, has also been recommended.

#### OTHER GENITO-URINARY INFECTIONS

For genito-urinary infections other than gonorrhea adults should receive an initial oral dose of 0 o5 Gm./kg.

of body weight (about 0 023 Gm./lb.), followed by 1/3 of the initial dose every 4 hours day and night until the temperature has been normal for from 3 to 5 days. In very serious infections, somewhat higher dosage may be given. For a complete discussion of dosage, see *Lederle* literature; or, New and Nonofficial Remedies, edition

1943.
During treatment with sulfadiazine, sulfathiazole or sulfapyridine, alkalis sufficient to maintain an alkaline urine should be administered unless contraindicated; and liquids should be given to produce a daily urinary output of between 1,000 and 1,500 cc. It is important to establish a full urinary output prior to the institution of sulfonamide parenteral therapy.

LEDERINE NABORAL ORIES

are all the therapeutic properties of brewers' yeast incorporated in

a much higher natural potency of riboflavin and thiamine than average brewers' yeast tablets.

Six White's Natural Vitamin
B Complex Tablets (average adult daily dosage) provide:

the thismine potency of
9 to 16 average brewers'
yeast tablets.

and the ribediavin potency of 12 to 33 average
through yearst tablets.

WHITE'S Natural Vitamin B Complex Tablets are brewers' yeast PLUS. They provide all factors of the entire B Complex, concentrated from two all-natural sources:

- a. high potency brewers' yeast
- b. specially processed dried extract of corn

The advantages of White's Natural Vitamin B Complex Tablets over the average brewers' yeast tablets are:

1. Fewer tablets are required for average dosage—less likelihood of flatulence or digestive upset.

- 2. Nicotinic acid, pantothenic acid and pyridoxine, as well as thiamine and riboflavin, are all present in measured and declared amounts. You can readily appraise and compare White's formula.
- 3. Lower cost to patient—on a potency basis, less than that of the average brewers' yeast tablet.

Supplied in bottles of 90, 225, 1000 and 5000 tablets.

Ethically promoted—not advertised to the laity.

White Laboratories, Inc., Pharmaceutical Manufacturers, Newark 7, N.J.

# THE SUNSET YEARS AND

# Adequate Nutrition

As the degenerative processes gain the upper hand during the last decade or two of life, profound changes occur in many metabolic mechanisms. The gastrointestinal tract for example becomes less tolerant of abuses, and difficulty is experienced in digesting some foods which formerly did not prove troublesome. The loss of vigor characteristic of senescence can easily be aggravated to a point of incapacitation if eating habits are not altered to prevent nutritional deficiencies. For only by properly satisfying the nutritional requirements can strength be maintained.

Ovaltine is well tolerated by elderly persons. It supplies a wealth of nutrients which are frequently lacking in the diets chosen during advanced years: biologically adequate protein, B complex vitamins, essential minerals, and vitamins A and D. The high content of diastatic malt makes Ovaltine a valuable aid in the digestion of starchy foods. This delicious food drink appeals to older persons, hence it can be included in their diet three times daily without meeting with objection or resistance. The Wander Company, 360 North Michigan Avenue, Chicago, Illinois.

AL DIURETIC

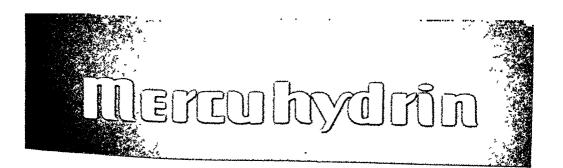

# Better Tolerated Locally

After years of scientific research, Lakeside announces a new mercurial diuretic... MERCUHYDRIN\* This new diuretic, in addition to being well tolerated systemically, is significantly free from reaction at the site of injection when given intramuscularly. Mercuhydrin is rapidly absorbed following intramuscular injection and is compatible with the local tissues; hence, its freedom from reaction by this route. Accidental extravasation during intravenous injection has not resulted in serious tissue damage. Mercuhydrin thus may be administered by either route with complete assurance... Mercuhydrin is indicated in the edema of cardiorenal disease, nephrosis, and ascites of liver disease. Its diuretic action has been shown to be fully satisfactory, both as to quantity of urine excreted and duration of effect, in these conditions. Years of careful experiment and clinical work have established its safety and therapeutic value.

\*A derivative of urea, the sodium salt of methoxyoximercuripropylsuccinylurea with theophylline. LAKESIDE LABORATORIES, Milwankee, Wis.

Mercuhydrin is supplied both in 1 cc. and 2 cc. ampuls.

Literature and samples on request.

(H. W. & D. Preparation of Corpus Luteum)

Lutein Extract is indicated in obstetrical complications, especially threatened and habitual abortion.\* Injections of Lutein Extract in adequate dosage inhibit uterine contractions.

A controlled clinical study showed that patients receiving Lutein Extract were carried to delivery in a high percentage of cases as compared with those not treated with Lutein. In these cases it may be given intravenously. There were no untoward reactions when relatively large doses were given by the intravenous route.

Lutein Extract in smaller doses is also administered intramuscularly in nausea and vomiting of pregnancy and in relieving the symptoms of ovarian insufficiency.

Lutein Extract is supplied in 3 c.c. and 1 c.c. size ampules, packed in boxes of 10 or 100 ampules.

Literature and natural color illustrations will be sent to physicians on request.

# Federal Emergency Maternal and Infant Care Program in New York State

Summarizing the enormous amount of work already done on this program by the Medical Society of the State of New York and the officers of State agencies, the Council Committee on Public Health and Education (and subcommittees) submits a report to the physicians of the State on page 295 of this issue. Immediately following the Council Committees' report will be found the Information Circular for Physicians (E. M. I. C. No. 4, Revised to December 1, 1943) of the New York State Department of Health.

No one who reads these reports can fail to be impressed with the complexity of the problems to be solved. Four conferences of the Council Committees of the State Society and the Department of Health both of the State and of New York City had to be held before the State Department of Health could and did submit "its first proposal for an operating plan under the rules and regulations of the Childrens' Bureau on June 18, 1943." Obviously, maternity and infant care for the dependent wives and infants of servicemen in the designated classes had to be and was furnished by the physicians of the State while these discussions as to details of the administration of the plan were being carried out. "Immediately after returning from Washington," says the report, "Dr. Edward Godfrey, Jr., State Commissioner of Health, requested a conference with the appropriate committees of the Medical Society of the State of New York. The first meeting was held on April 7, 1943." Many features of the Childrens' Bureau program were jointly discussed at this meeting.

"Although the members of the conferences were dissatisfied with several aspects of the program, there never was any objection to its objective; namely, to assure good maternity and infant care for the families of men in the armed services." Criticisms of certain basic requirements of the plan proposed by the Childrens' Bureau composed the agenda of the first four meetings, and as a result "the State Commissioner of Health made vigorous presentation to the Childrens' Bureau for changes in the plan."

Whereas Congress made funds available in March, 1943, and the conferences began on April 7, 1943, it was not until June 18, 1943. that the Commissioner of Health of the State of New York, responsible for the administration of the Federal program in the State, could prepare and submit to the joint conferences his first operating plan. This plan, after very thorough discussion, was finally put into effect in July 1, 1943.

At subsequent conferences "Many details of the plan and several major issues which had not been presented previously to the Childrens' Bureau were discussed and further adjustments in the plan are anticipated." These comprise possible early revision of the present policies respecting health supervision, fairer definition of the types and extent of the illnesses which the physician is expected to care for under the

# Universal (O) Blood Transfusion

The desirability of a readily available blood safe for immediate and unmatched transfusion is too obvious to require elaboration. The use of universal blood donors was first reported by Ottenberg<sup>1</sup> in 1911. Because the serum of universal (O) donors has a titer of agglutinins higher than 1:16 in 3 per cent of all donors, the indiscriminate use of such serums not infrequently leads to transfusion accidents. For this reason prohibition of such transfusions has been incorporated in the New York State Sanitary Code Unless actual titration demonstrates a titer of agglutinins in universal (O) blood so low as to be innocuous, a time-consuming laboratory procedure, the sanitary code does not permit such blood to be used for transfusions. Witebsky and his collaborators<sup>2</sup> solved the problem of isoagglutination by neutralizing isoagglutinins, anti-A and anti-B, by adding the homologous A and B antigens to the O blood, thus presumably making the treated universal blood relatively safe for emergency transfusions.

A simpler, safe, universal blood has recently been devised.3 O cells contain no agglutinogen, and pooled plasma rarely gives rise to genuinely untoward reactions. The suspension of the harmless O red cell in pooled plasma forms a synthetic blood, use of which promises to be

practically devoid of undesirable reactions. This method also permits the utilization of surplus red cells and plasma, a timely measure of economy. If red cells alone are needed by the recipient they can be suspended in a saline or glucose solution of an isotonic nature. If, for some reason, all of the synthetic universal blood is not used, or if the time allotted for the safety of such a mixture has been exceeded, the plasma can be reclaimed and again used as such. These factors create an economical as well as a relatively safe procedure for urgent transfusions which cannot await laboratory testing and cross-

The simplicity of this mixture of nonantigenic O erythrocytes and pooled plasma lends itself to ready and extensive usage. Large-scale studies are needed to further test and corroborate the safety of such blood for transfusion. When ample statistics are made available, and the risk entailed can be mathematically demonstrated to be minimal, this new method of giving universal blood for emergency transfusions then promises to be widely employed.

# Announcement

# 1944 ANNUAL MEETING

Medical Society of the State of New York

The 138th Annual Meeting of the Medical Society of the State of New York will be held Monday, May 8, to Thursday, May 11, 1944, inclusive, at Hotel Pennsylvania in New York City

COUNCIL COMMITTEE ON CONVENTION

## FREQUENCY AND COURSE OF CANCER IN DIABETICS

FRIEDRICH ELLINGER, M.D., New York City, and Harold Landsman, M.D., Jamaica, New York

CANCER and diabetes are two diseases which have some features in common: both are diseases of the aging population predominantly, both occur frequently, and both are characterized by a disturbance in the carbohydrate metabolism. Simultaneous appearance of cancer and diabetes in the same patient is, therefore, apt to attract interest from various points of view.

The first extensive study in this field was the paper "Diabèle et néoplasmes" by V. Tuffier,¹ published in Paris in 1888. In this paper 54 cases of diabetes associated with different kinds of tumors (thirty-three of which were malignant) were reported. In Tuffier's opinion, intestinal cancers showed remarkably slow growth and the tumors were more prone to ulceration. Malnutrition was given as the explanation for the slow growth.

Subsequent writers on the subject of cancer and diabetes reported more or less casually on the association of the two diseases. Schäfer, in a thesis from the University of Basel (Switzerland), published in 1931, collected 136 cases from the world literature, including Tuffier's material. A recent comprehensive study is the paper "Diabetes and Cancer," published in this country in 1934 by Alexander Marble.

While some of the preceding papers considered the occurrence of cancer in diabetics chiefly from the diabetic point of view, this paper, based on clinical material, emphasizes the oncologic aspect of this problem.

## Clinical Material

During the years 1933 to 1941 a total of 1,280 patients have been recorded as suffering from diabetes mellitus at Montefiore Hospital for Chronic Diseases in New York City. Out of these 1,280 diabetics 39 or 3.04 per cent had malignant tumors. These 39 cases of malignant tumors in diabetics are listed in Table 1 (page 260).

As can be seen, 33 out of the 39 patients died, 2 (Cases 17 and 24) from other causes than cancer. Four patients are still alive (Cases 11, 33, 38, 39) and in 2 cases (Cases 34 and 35) there was no follow-up.

From the Radiation Therapy Department, Montefiore Herpital for Chronic Diseases, New York City.

Formerly research radiotherapist, Montefiore Hospital; now research associate in radiology, Long Island College of Medicine, Brooklyn.

Formerly assistant resident physician, radiotherapy department, Montefiore Hospital; now Captain, (MC),

Autopsies have been performed in 23 out of 33 deceased patients.

Age and sex distribution of the 39 cancer cases is shown in Table 2.

TABLE 2.-Age AND SEX DISTRIBUTION

Sex	Total Cases	Age, 35-44	Age, 45-54	Age, 55-64	Age, 65-74	Age, Over 75
Male	12	0	3	4	3	2
Female	27	2	5	9	10	1
Total	39	2	8	13	13	3

#### Tumors

Site and frequency of tumors are shown in Table 3. The figures in parentheses refer to the numbers of the cases as listed in Table 1.

TABLE 3.-Site and Frequency of Tomors

	Location of Tumors	Number of Cases
1.	Gastrointestinal tract	14
	Rectum (4, 17, 18, 19, 21)	
	Sigmoid (38)	
	Cecum (5)	
	Colon (34)	
	Stomach (6, 20, 27)	
	Esophagus (26, 35)	
	Pancreas (31) Female sex organs	13
4.	Breast (1, 2, 3, 16, 28, 38)	10
	Uterus (11, 12, 24, 36)	
	Vagina (29)	
	Ovaries (25, 37)	
3.		3
	Lung (8, 9, 30)	
4.		9
	Skin, basal carcinoma (33)	
	Thyroid (10, 12)

#### Diabetes

The duration of diabetes in our patients varied from four months (Case 38) up to twenty-five years (Case 15).

The classification of diabetes has been based on the highest amount of daily units of insulin the patient received at all times. Similar to the procedure of Wilder a group classification has been made on this basis as follows:

Group A: Mild Diabetes: No insulin up to 20 units of insulin daily.

Group B: Moderate Diabetes: 21 to 40 units of insulin daily.

Group C: Severe Diabetes: More than 41 units daily.

By including in Group A cases without insulin and with small amounts of insulin, this classification takes into consideration the criticism raised by Joslin<sup>5</sup> against such a procedure, based on units of insulin. Joslin objects to the comparison of patients who do not take insulin with those who take insulin "because few doctors use identical diets, and few doctors have the same rules for the use or nonuse of insulin." This consideration is especially important in our group of patients, where many of the patients received part of their diabetic treatment outside the hospital. This classification considers, furthermore, the special condition of the diabetes patient after the age of 40, as recently explained by Handelsman and Bradford.6 Some who previously got along without insulin may require it as they grow older, while others who received insulin previously, might do well without insulin, by reduction in body weight.

The therapy of diabetes in our cases was diet and insulin. Out of the 39 cases all but 10 (Cases 6, 16, 18, 29, 30, 32, 35, 36, 37, 39) received insulin. The doses ranged from 5 to 100 units daily.

# Relationship Between Cancer and Diabetes

The temporal relationship between the onset of cancer symptoms or discovery of the tumor and that of diabetes is given in Table 5.

#### TABLE 5

Tumor observed before diabetes In 7 cases Cases 2, 3, 5, 16, 17, 23, 39 In 20 cases Cases 7, 9, 10, 11, 12, 15, 18, 19, 20, 24, 25, 26, 27, 28, 31, 33, 34, 35, 36, 37 Tumor and diabetes observed simultaneously In 12 cases Cases 1, 4, 6, 8, 13, 14, 21, 22, 29, 30, 32, 38

## Discussion

In evaluating the clinical material presented in this paper, we shall try to answer some of the questions which arise from the observation of malignant growth and diabetes in the same patient:

1. Does Malignant Growth Occur on the Basis of Diabetes, or Are Diabetic Symptoms Produced by Malignant Growth?-Table 5 seems to provide an answer to this question. As can be seen from this table, in only 7 out of 39 cases was the tumor discovered prior to diabetes. This agrees with the observations of Marble,3 who found that out of 161 cases in his group, in 132 the onset of diabetes preceded that of cancer symptoms. Our observations seem to give additional proof for the opinion expressed by Marble that "one would seem to be dealing in general with a group of patients who later developed cancer rather than with a group of patients with malignant diseases who developed diabetes."

2. Is the Diabetic More Likely to Develop Cancer?—In our series of 1,280 recorded diabetics we found 39 cases of cancer, or a cancer incidence of 3.04 per cent. This figure is in agreement with the cancer incidence of 2.95 per cent derived from a collected material of 14,332 cases of diabetes as listed in Table 6.

Warren <sup>18</sup>	1938	527	47	8.90
Total		14,332	422	2.95

For the proper evaluation of these data the comparison of the cancer incidence in diabetics with the cancer incidence in the general population is necessary. The evaluation on the basis of death statistics meets serious difficulties, as explained by Marble.3

In the state of New York, cancer is a reportable disease. Through the courtesy of Dr. Louis C. Kress, Director of the Division of Cancer Control of the New York State Department of Health in Albany, a tabulation of pertinent data made by Mr. Weinstein, Statistician of the Division of Cancer Control, has been made available to us.\* The data are presented in Table 7.

As can be seen from Table 7, the total rate of cancer incidence for the age group 35 to 74 years in the general population was 460.7 per 100,000 population, or 0.46 per cent. In

<sup>\*</sup> We wish to express our gratitude to Dr. Kress and Mr Weinstein for permission to use this material.

TABLE 7.—CANCER INCIDENCE, STATE OF NEW YORK 1941—RATE PER 100,000 POPULATION

Age	Total	Male	Female
35-44 45-54	$\frac{142.1}{331.4}$	$84.0 \\ 239.4$	$\frac{200.4}{427.6}$
55-64 65-74	693.6 1,186.0	$615.9 \\ 1,215.4$	771.4 1,159.1
Total	460.7	393.7	527.9

the opinion of Mr. Weinstein, "It is evident that the incidence for the total experience is much less than the 3 per cent found in the diabetic population."

Since all of the reports on cancer incidence in diabetics summarized in Table 6 show at least a twice as high cancer incidence in diabetics as that found in the general population, the significance of the higher cancer incidence in diabetics seems to be well supported. The conclusion seems justified that the diabetic seems to be more liable to develop cancer. Even if it is as yet premature to determine the extent to which a diabetic is more likely to develop cancer, the fact of such a likelihood is not only of great clinical but also of great social interest; e.g., with respect to life insurance problems.

3. Site and Frequency of Cancer in Diabetics.—The extraordinarily high incidence of cancer of the pancreas observed by Marble<sup>3</sup> in his group of diabetics with cancer made it advisable to study the site and frequency of malignant tumors in our series of patients. The pertinent data are listed in Table 3. As can be seen, there are no unusual features: the first and second place are occupied by tumors of the gastrointestinal tract and female sex organs, respectively. This is the distribution usually found also in non-diabetics.

4. Course of Malignant Tumors in Diabetics. -As mentioned above, Tuffier had already noted remarkably slow growth of malignant tumors in diabetics. In 1903 Boas14 expressed the opinion that cancer developing in a patient with severe diabetes shows a very progressive course, whereas a cancer developing in mild diabetes is apparently less progressive. These observations suggest some influence of the diabetes on malignant growth. For the study of the possible influence of diabetes on the course of malignant growth in our series, the average lifetime in years after discovery of tumors has been listed in Table 8, and these data related to the severity of the diabetes. The classification of the diabetes is used as outlined above.

Table 8 shows in a statistically significant way the decrease in the average lifetime of the tumor patient with increasing severity of his diabetes. Our results confirm the opinions

TABLE 8.—Comparison of the Average Inferine After Onset of Tumors and the Severity of Diabetes

			===
Diabetes	Number of Cases	Average Lifetime in Years	m*
Group A: mild Group B: moderate Group C: severe	23 7 5	4.6 2.7 0.9	±0.99 ±0.41 ±0.72

\* m denotes the mean of the average and has been figured according to the formula,  $m = \frac{\sigma}{\sqrt{n}} (\pm \sigma = \text{standard deristion}; n = \text{number of cases}).$ 

expressed by Tuffier<sup>1</sup> and Boas<sup>14</sup> that the disbetic condition influences malignant growth.

5. Explanation of Particular Course of Malignant Growth in Diabetes.—The observation that the average lifetime of cancer patients decreases with the severity of the diabetes is not surprising from the clinical point of view, considering the fact that both diseases are highly malignant.

The question, however, could be raised whether the decline in the average survival time of tumor patients as shown in Table 8 is due to the malignant growth, or whether the more severe diabetes terminates the life of the patient before the malignant growth causes death. The fact that with the use of insulin in the treatment of diabetic coma, which caused death in 63.8 per cent of diabetics in the period 1897-1914, has declined as the cause of death to 3.6 per cent in 1937 in Joslin's series of diabetics, seems to be the answer to this question. "Insulin has almost eliminated diabetic death per se ..... The diabetic dies of his complications and not of his disease (Joslin, op. cit., page 283)." Since none of our patients with cancer and diabetes died in coma but all of the cases considered as moderate or severe diabetes received insulin until death, it seems justifiable to attribute the death to the malignant neoplasm.

Besides, a precipitant course of malignant growth developing in a patient with severe diabetes is easily understandable in the light of results of experimental cancer research.

Experiments by Alsteyne and Beebe, <sup>15</sup> Goldfeder, <sup>16</sup> Lustig and Wachtel, <sup>17</sup> Randoni, <sup>18</sup> Takizawa, <sup>19</sup> v. Witzleben, <sup>20</sup> and others have shown that glucose injections enhanced the growth of malignant tumors. According to Cori and Cori<sup>18</sup> the carbohydrate content of malignant tumor tissue is less than that of normal tissues and increases after injection of glucose up to 400 per cent. As another proof of the increased growth tendency of tumors\* after injection of carbohydrates their sensitization to the effects

<sup>\*</sup> Growth is accompanied by increased cell metabolism. Usually an increase in cell metabolism is accompanied by an increase in radiosensitivity (Ellinger, 22 page 273).

TABLE 9

\* Patient died from heart failure. † Patient still alive; received neither surgery nor radiation therapy.

of roentgen rays may be mentioned, as shown by Holzknecht,23 Inouye,24 Mayer,25 and Osima.26 "In human individuals with spontaneous dia-

betes, there exists not only an overproduction of glucose in the liver, but also a diminished efficiency in the combustion of glucose in the tissues" (Joslin, op. cit., page 95). Thus diabetes creates a condition similar to that which glucose injections do. The progressive course of malignant tumors in patients suffering from a severe diabetes, as clinically observed, finds its experimental support.

Far more startling appears the fact that there seems to be a slowing down of malignant growth developing in the course of mild diabetes. In addition to the remarks of Tuffier1 and Boas14 as to this point, there are similar observations noted in more recent clinical reports: Krelenstein<sup>27</sup> mentioned 33 per cent absolute cures in patients suffering from carcinoma uteri and diabetes, while in nondiabetics with carcinoma uteri the absolute cures amounted to only 20 per cent. Gal28 and Kleine29 reported good results with radiation therapy in cases of carcinoma uteri combined with diabetes. Gal<sup>28</sup> attributes the good results to a supposedly increased radiosensitivity of the neoplasms in diabetes. This increased radiosensitivity is derived from the experiments with injection of glucose as quoted above. However, this statement is in some contradiction to the observations of Krelenstein, whose cases had been treated by surgery as well as radiation therapy.

With respect to these clinical observations, the relatively high average survival rate of tumor patients with mild diabetes as noted in Table 8 is interesting. The significance of this figure is supported by the fact that 9 out of our 39 patients with diabetes lived for 5 years or longer after discovery of the tumor. For closer analysis these cases have been listed in Table 9. Special attention has been given to the age at which the tumor started, the diabetic condition of the patient, and whether the patient received radiation therapy.

As can be seen from Table 9, the age of onset

of tumors rules out the assumption that old age contributed to the slow growth of the tumors, because with the exception of Case 4, all tumors started in the fourth or fifth decade of life, and in Case 37 at 38 years of age. Since only 4 out of the 9 patients received radiation therapy, the supposedly increased radiosensitivity of tumors in diabetics seems to be eliminated as a possible cause for the considerable survival time of the tumor bearers. The fact, however, that all but one case (Case 5) according to our classification belonged to the group who had "mild diabetes," is noteworthy. It seems that in the mild diabetes the course of malignant growth is slowed down.

6. What Explanation Can Be Advanced for the Understanding of Retarded Tumor Growth in Mild Diabetes?—As early as 1885, Freund30 in Vienna was able to demonstrate an increase in the blood sugar level in 10 patients suffering from malignant tumors, irrespective of the histology of the tumors. After surgical removal of the neoplasms, the blood sugar returned to normal in all but one case. This patient showed a recurrence. The increase in blood sugar in patients suffering from malignant tumors has been confirmed in many quarters. It has been found, however, that this is not a constant result (Kelly, 31 Rhodenburg, 32 Theis and Stone, 33 Woodward and Fry.34

Another interesting clinical observation was reported by Braunstein.35 He noticed that in diabetics with fast-growing tumors the blood sugar level decreased. "It seems as if cancer behaves in some instances as an antagonist to the diabetes." After surgical removal of the tumors, in some instances a recurrence of sugar excretion in urine was noted.

Additional proof of Braunstein's observations can be found in the statement by Marble3 that in his series some diabetics with malignant tumors, who required insulin in the beginning. remained sugar-free without insulin later on. Marble assumes that the apparent improvement in the diabetic condition is probably due to undernutrition. We were able to confirm Marble's observation in 7 of our patients (Cases

TABLE 7.—CANCER INCIDENCE, STATE OF NEW YORK 1941—RATE PER 100,000 POPULATION

Age	Total	Male	Female
35-44 45-54	$\frac{142.1}{331.4}$	84.0 239.4	200.4 427.6
55-64 65-74	693.6 1,186.0	615.9 $1,215.4$	771.4 1,159.1
Total	460.7	393.7	527.9

the opinion of Mr. Weinstein, "It is evident that the incidence for the total experience is much less than the 3 per cent found in the diabetic population."

Since all of the reports on cancer incidence in diabetics summarized in Table 6 show at least a twice as high cancer incidence in diabetics as that found in the general population, the significance of the higher cancer incidence in diabetics seems to be well supported. The conclusion seems justified that the diabetic seems to be more liable to develop cancer. Even if it is as yet premature to determine the extent to which a diabetic is more likely to develop cancer, the fact of such a likelihood is not only of great clinical but also of great social interest; e.g., with respect to life insurance problems.

3. Site and Frequency of Cancer in Diabetics.—The extraordinarily high incidence of cancer of the pancreas observed by Marble<sup>3</sup> in his group of diabetics with cancer made it advisable to study the site and frequency of malignant tumors in our series of patients. The pertinent data are listed in Table 3. As can be seen, there are no unusual features: the first and second place are occupied by tumors of the gastrointestinal tract and female sex organs, respectively. This is the distribution usually found also in non-diabetics.

4. Course of Malignant Tumors in Diabetics. -As mentioned above, Tuffier had already noted remarkably slow growth of malignant tumors in diabetics. In 1903 Boas<sup>14</sup> expressed the opinion that cancer developing in a patient with severe diabetes shows a very progressive course, whereas a cancer developing in mild diabetes is apparently less progressive. These observations suggest some influence of the diabetes on malignant growth. For the study of the possible influence of diabetes on the course of malignant growth in our series, the average lifetime in years after discovery of tumors has been listed in Table 8, and these data related to the severity of the diabetes. The classification of the diabetes is used as outlined above.

Table 8 shows in a statistically significant way the decrease in the average lifetime of the tumor patient with increasing severity of his diabetes. Our results confirm the opinions

TABLE 8.—Comparison of the Average Lifetime Affir Onset of Tumors and the Severity of Diabetes

\* m denotes the mean of the average and has been figured according to the formula,  $m = \frac{\sigma}{\sqrt{n}} (\pm \sigma = standard deristion: n = number of cases).$ 

expressed by Tuffier<sup>1</sup> and Boas<sup>14</sup> that the diabetic condition influences malignant growth.

5. Explanation of Particular Course of Malignant Growth in Diabetes.—The observation that the average lifetime of cancer patients decreases with the severity of the diabetes is not surprising from the clinical point of view, considering the fact that both diseases are highly malignant.

The question, however, could be raised whether the decline in the average survival time of tumor patients as shown in Table 8 is due to the malignant growth, or whether the more severe diabetes terminates the life of the patient before the malignant growth causes death. The fact that with the use of insulin in the treatment of diabetic coma, which caused death in 63.8 per cent of diabetics in the period 1897-1914, has declined as the cause of death to 3.6 per cent in 1937 in Joslin's series of diabetics,6 seems to be the answer to this question. "Insulin has almost eliminated diabetic death per se ..... The diabetic dies of his complications and not of his disease (Joslin, op. cit., page 283)." Since none of our patients with cancer and diabetes died in coma but all of the cases considered as moderate or severe diabetes received insulin until death, it seems justifiable to attribute the death to the malignant neoplasm.

Besides, a precipitant course of malignant growth developing in a patient with severe diabetes is easily understandable in the light of results of experimental cancer research.

Experiments by Alsteyne and Beebe, <sup>15</sup> Goldfeder, <sup>16</sup> Lustig and Wachtel, <sup>17</sup> Randoni, <sup>18</sup> Takizawa, <sup>19</sup> v. Witzleben, <sup>20</sup> and others have shown that glucose injections enhanced the growth of malignant tumors. According to Cori and Cori<sup>21</sup> the carbohydrate content of malignant tumor tissue is less than that of normal tissues and increases after injection of glucose up to 400 per cent. As another proof of the increased growth tendency of tumors\* after injection of carbohydrates their sensitization to the effects

of roentgen rays may be mentioned, as shown by Holzknecht, <sup>23</sup> Inouye, <sup>24</sup> Mayer, <sup>25</sup> and Osima. <sup>26</sup>

"In human individuals with spontaneous diabetes, there exists not only an overproduction of glucose in the liver, but also a diminished efficiency in the combustion of glucose in the tissues" (Joslin, op. cit., page 95). Thus diabetes creates a condition similar to that which glucose injections do. The progressive course of malignant tumors in patients suffering from a severe diabetes, as clinically observed, finds its experimental support.

Far more startling appears the fact that there seems to be a slowing down of malignant growth developing in the course of mild diabetes. In addition to the remarks of Tuffier and Boas 14 as to this point, there are similar observations noted in more recent clinical reports: Krelenstein<sup>27</sup> mentioned 33 per cent absolute cures in patients suffering from carcinoma uteri and diabetes, while in nondiabetics with carcinoma uteri the absolute cures amounted to only 20 per cent. Gal23 and Kleine23 reported good results with radiation therapy in cases of carcinoma uteri combined with diabetes. Gal28 attributes the good results to a supposedly increased radiosensitivity of the neoplasms in diabetes. This increased radiosensitivity is derived from the experiments with injection of glucose as quoted above. However, this statement is in some contradiction to the observations of Krelenstein, whose cases had been treated by surgery as well as radiation therapy.

With respect to these clinical observations, the relatively high average survival rate of tumor patients with mild diabetes as noted in Table 8 is interesting. The significance of this figure is supported by the fact that 9 out of our 39 patients with diabetes lived for 5 years or longer after discovery of the tumor. For closer analysis these cases have been listed in Table 9. Special attention has been given to the age at which the tumor started, the diabetic condition of the patient, and whether the patient received radiation therapy.

As can be seen from Table 9, the age of onset

of tumors rules out the assumption that old age contributed to the slow growth of the tumors, because with the exception of Case 4, all tumors started in the fourth or fifth decade of life, and in Case 37 at 38 years of age. Since only 4 out of the 9 patients received radiation therapy, the supposedly increased radiosensitivity of tumors in diabetics seems to be eliminated as a possible cause for the considerable survival time of the tumor bearers. The fact, however, that all but one case (Case 5) according to our classification belonged to the group who had "mild diabetes," is noteworthy. It seems that in the mild diabetes the course of malignant growth is slowed down.

6. What Explanation Can Be Advanced for the Understanding of Retarded Tumor Growth in Mild Diabetes?—As early as 1885, Freund<sup>30</sup> in Vienna was able to demonstrate an increase in the blood sugar level in 10 patients suffering from malignant tumors, irrespective of the histology of the tumors. After surgical removal of the neoplasms, the blood sugar returned to normal in all but one case. This patient showed a recurrence. The increase in blood sugar in patients suffering from malignant tumors has been confirmed in many quarters. It has been found, however, that this is not a constant result (Kelly,<sup>31</sup> Rhodenburg,<sup>32</sup> Theis and Stone,<sup>33</sup> Woodward and Fry.<sup>34</sup>

Another interesting clinical observation was reported by Braunstein.<sup>35</sup> He noticed that in diabetics with fast-growing tumors the blood sugar level decreased. "It seems as if cancer behaves in some instances as an antagonist to the diabetes." After surgical removal of the tumors, in some instances a recurrence of sugar excretion in urine was noted.

Additional proof of Braunstein's observations can be found in the statement by Marble<sup>3</sup> that in his series some diabetics with malignant tumors, who required insulin in the beginning, remained sugar-free without insulin later on. Marble assumes that the apparent improvement in the diabetic condition is probably due to undernutrition. We were able to confirm Marble's observation in 7 of our patients (Cases

<sup>†</sup> Patient still alive; received neither surgery nor radiation therapy.

3, 4, 13, 14, 15, 20, 23) to whom insulin had been given in the beginning, and after cessation of insulin treatment in the course of tumor development the blood sugar level dropped to almost normal values (100–140 mg. per cent) and the urine could be kept sugar-free with a moderate diet.

Thus nature has provided most interesting experiments, which, in conjunction with the studies of Warburg and his associates<sup>36</sup> on the metabolism of tumor cells, may offer an explanation for the clinical observation of retarded growth of malignant neoplasms in mild diabetes.

According to these studies it is a peculiarity of tumor cells to glycolize sugar (produce lactic acid) under aerobic conditions as well as under anaerobic conditions; whereas normal cells usually oxidize sugar, and only if oxygen is lacking to make use of glycolysis. Warburg's work has been confirmed by Dickens and his associates.37 They as well as Crabtree38 have shown in addition that the metabolism of tumor cells is characterized by a respiratory quotient that is below unity (0.75 to 0.9). Whereas the normal cell splits dextrose into lactic acid, of which 80 per cent is resynthetized to glycogen and only 20 per cent is split off to form carbon dioxide and water, this glycogen resynthesis is suppressed in tumor cells. The energy requirement of tumor cells is covered by glycolysis chiefly. This, however, is a pretty wasteful use of carbohydrates, because only 42 per cent of the energy obtainable by oxidation is obtained by glycolysis. To cover its energy requirement the tumor tries to obtain as much carbohydrate from the host's body as possible. This has been shown experimentally by Tadenuma, Hotta, and Homa<sup>39</sup> and Cori and Cori.<sup>40</sup> They were able to demonstrate in chickens, in whose one wing a tumor had been grafted, that the venous blood coming from the tumor wing showed a considerably lower sugar content (having passed through the tumor) than the venous blood of the normal wing. The more or less increased blood sugar level of nondiabetic tumor hosts can thus easily be understood as an expression of carbohydrate mobilization from the storage places, to cover the greater requirement of the malignant growth.

Entirely different are the conditions in the diabetic tumor host; here, the increased blood sugar level is an expression of an overproduction of carbohydrates in conjunction with an interference of proper storage of carbohydrates. In severe diabetes, where carbohydrate formation reaches excessive values, metabolizing even fats and proteins to a large extent into carbohydrates, the amounts of glucose thus avail-

able are sufficient to initiate and support tumor growth without pronounced changes in the diabetic condition. In mild diabetes, however, the available amounts of glucose seem to be less sufficient. They may initiate tumor growth, but the disturbed carbohydrate metabolism of the diabetic host seems incapable of keeping pace with the increasing demands of the growing tumor, expression of which is the apparent amelioration of the diabetic symptoms, as observed by others and ourselves.

To resume the above-mentioned experimental and clinical observations, the answer to the question as to the retarded growth of malignant tumors in mild diabetes seems to be a competitive carbohydrate metabolism which to a certain extent starves the tumor. In support of this hypothesis results of recent experiments by Tannenbaum<sup>41</sup> may be quoted. This author was able to demonstrate that caloric restriction of the food intake per se inhibits in mice the appearance and growth of spontaneously occurring tumors as well as of induced ones.

The hypothesis of competitive carbohydrate metabolism seems to offer a suitable basis for the explanation of the slow growth of malignant tumors in mild diabetes and of the relatively high percentage (about 25 per cent) of survivors for five years and longer in our series of tumor patients with diabetes. This hypothesis explains, furthermore, the good results of radiation therapy in this condition as reported by Gal. Apparently they are not exclusively due to increased radiosensitivity, as Gal assumes, but are due to the fact that in these patients with a slowing down of the malignant primary tumor, the spread and growth of metastases is apparently slowed down too. The fact that equally good results were obtained by surgical treatment of carcinoma of the uterus in diabetics, as reported by Krelenstein,27 is emphasizing this opinion.

### Summary

- 1. Among 1,280 cases of diabetes mellitus recorded at Montefiore Hospital, 39 cases of malignant tumors have been found. This cancer incidence of 3.04 per cent is in agreement with a cancer incidence of 2.95 per cent derived from 14,332 cases of diabetes collected from the world literature.
- 2. Since the cancer incidence in a general population (state of New York in 1941) was 0.46 per cent, that means a definitely higher cancer incidence in diabetics.
- 3. In agreement with previous observations, a more virulent course of malignant growth in diabetics has been found with increasing severity of the diabetic condition. The average lifetime after onset of tumor symptoms in the series

presented in this paper decreased from 4.6 years in mild diabetes to 0.9 years in severe diabetes.

- 4. In agreement with the remarkably long average survival time of 4.6 years in mild diabetes, a closer analysis showed that 9 out of the 39 patients with cancer and diabetes lived for five years and longer after onset of tumor symptoms. All but one of these cases belonged to the group of mild diabetes. It is highly suggestive that mild diabetes produces a retardation of malignant growth and of spread and growth of metastases.
- 5. Results of experimental cancer research as well as some clinical observations are quoted in explanation of the higher cancer incidence in diabetics as well as of the apparent retardation of malignant growth in mild diabetes. Both phenomena could be traced to the abnormal carbohydrate metabolism.\*

## PROGRESS IN CANCER CONTROL

ć, ÷

١٠

ļ

;

€,

Progress in cancer control in the last twentyfive years while not dramatic has been steady and based upon scientific principles. The main lines of progress have been as follows:

1. The continued development of irradiation as a method of treatment and clarification of its advantages and limitations.

The constant improvement in surgical technic and the standardization of the surgical treatment of some forms of cancer.

3. The discovery of numerous carcinogenic substances and the proof of their importance in certain types of human cancer.

4. The discovery of the relationship between hormones and some cancers.

5. The institution of the lay cancer educational program designed to educate the individual in the necessity of seeking medical advice while the cancer is localized.

The general recognition by the medical profession that cancer is at first a localized process and then is curable.

7. The establishment of departments concerned with the control of cancer by the national and many state governments.

8. The more generous financial support of cancer research.

The organization of approved cancer clinics by the American College of Surgeons and by

some state health departments.

10. The incorporation of the study of cancer as a part of courses in biology in many high schools and colleges .- Bulletin, Women's Field Army, Iowa Division

<sup>\*</sup> Note: In the preparation of this paper the kind support of Drs. J. Freid and H. Goldberg, Radiotherapy Department, Montefiore Hospital, is thankfully acknowledged. The authors wish to express their gratitude for helpful discussions to Dr. A. Goldfeder, Department of Experimental Surgery, New York University, and to Dr. M. Handelsman, Chief, Diabetes Clinic, Long Island College of Medicine, Brooklyn

## RESPONSE TO TREATMENT OF PEPTIC ULCER

E. F. Driscoll, M.D., and A. H. Aaron, M.D., Buffalo

R EPORTS from the Medical Corps of the British Army have shown a surprisingly high incidence of peptic ulcer of the duodenum and stomach in their evacuated casualties. Payne and Newman<sup>1</sup> report 12.5 per cent of all cases evacuated to the United Kingdom during the three months prior to April 29, 1940, were gastric and duodenal ulcers. Graham and Kerr<sup>2</sup> in a large Military Hospital found 31 per cent of the medical inpatients were admitted because of gastrointestinal complaints, and of these 55 per cent had duodenal ulcers and 9 per cent gastric ulcers. Hurst<sup>3</sup> reports the high incidence of digestive disorders in soldiers and an analysis of 285 cases of dyspepsia included 224 proved ulcers.

Similar findings have been reported in our own forces4 and have occurred even before the men were under fire. It was the opinion of the British observers that the ulcers did not occur primarily as a result of military service but had been present in civilian life and were activated by Army food. They felt that psychosomatic influences played a minor role and that what actually happened was that men with peptic ulcer in civilian life were able to carry on their usual activities because they would choose their own bland foods and eat frequently. If they should have an attack it was possible for them to remain at home for a day or two on a milk diet, In the army, of course, this is impossible. Whatever the cause, peptic ulcer of the stomach and duodenum present one of the most important reasons for medical disability in military life. Likewise there is a sharp increase in the occurrence of peptic ulcer in civilian life.

With this in mind, it seemed to us that a review of the cases of peptic ulcer seen in the Outpatient Department of the Buffalo General Hospital would be not only interesting but timely and instructive, particularly if we were able to show one method of therapy far superior to any other. While the Outpatient Department has been in existence for about two decades, the gastrointestinal section was formed late in 1938, and is staffed by members who are trained and practicing gastroenterologists. All cases of gastrointestinal disease are referred to this clinic for consultation, diagnosis, and treatment. The service is of six months' duration and no specified methods of therapy are laid down, each man treating the patients he follows as he desires. A review of the cases then should show us a rather

wide variety of therapeutic agents with the utilization of any new or proved methods.

Peptic ulcer is not a new disease. The cause is unknown. Our best definition is that for some unknown reason a portion of the lining mucosa of the stomach or duodenum loses its power to resist the digestive action of the peptic acid gastric juice. In order to treat peptic ulcer, the practitioner must understand the disease and be able to educate the patient. Peptic ulcer is a chronic disease just as much as is diabetes, rheumatic heart disease, or arthritis. The ulcer will tend to heal but will also tend to recur. There is a definite emotional control of ulcer, and many recurrences are due to psychosomatic upsets. For example, one of our patients had a severe recurrence of ulcer symptoms when his wife left him. Another had a recurrence following an argument with his foreman at work. This means that the physician in taking the history must properly evaluate the environmental and emotional life of the patient. Furthermore, he must sit down with this patient and carefully explain the disease, its chronicity, its response to treatment, and its tendency to recur. Too much stress cannot be laid upon the education of the patient by the physician. No less time should be spent with the peptic ulcer patient than is spent with the diabetic. If the patient is properly educated as to his condition, we firmly believe that recurrences are preventable. He must understand that a recurrence will occur if he becomes overly fatigued, physically or mentally, if worry or emotional upsets intervene, or if he falls back into the habits of dietary indiscretion. The broad principles of treatment of any ulcer of the stomach or duodenum lie, first, in a control of the acidity of the gastric juice and, second, in an adequate nonirritating diet. Today the physician is confronted with a wide variety of substances for the control of gastric acidity. It is our purpose to attempt to determine the efficiency of the various antacids used for the patients with peptic ulcer in the gastrointestinal clinic and not to formulate any new method of treatment.

Case Reports

From the years 1939 to 1942 there were 19,681 cases admitted to the Outpatient Department of the Buffalo General Hospital and of these 669 or 3.39 per cent were referred to the gastrointestinal clinic. Of this latter group 100 patients or 14.94 per cent were diagnosed on adequate grounds as having peptic ulcer. Of these 100 patients 89 were males, 5 of

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 4, 1943.

whom were colored, and 11 were female, one of whom was colored—a ratio of 8 males to one female and 16 white to one colored. It is difficult to explain the lack of incidence of peptic ulcer in women because certainly women tend to be more nervous and excitable than men. There is a possibility that women have some form of a protective hormone present which tends to prevent the occurrence of peptic ulcer. On admission to the clinic the youngest patient was 18 years of age, the oldest 82, with an average age of 43.3. At the onset of symptoms the youngest patient was 15 years old, the oldest 74, and the average age 26.4. The longest duration of symptoms was thirty years, the shortest 121/2 hours, with an average of 7.5 years, a good example of the chronicity of peptic ulcer. These symptoms, of course, were not present continuously during this period of years but the symptoms recurred in some cases at intervals of a few weeks and others only at the end of a number of years. Twenty-one patients had complications in the past. Hemorrhage occurred sixteen times, perforation nine, and obstruction three times. These are the three chief complications of peptic ulcer.

Ninety-nine of these patients were x-rayed. The other one was a patient with perforation who reported to the clinic after leaving the hospital. The importance of x-ray examination in disease of the upper gastrointestinal tract cannot be overstressed. Not only does it confirm the clinical diagnosis of peptic ulcer, but most importantly, it locates the ulcer. Duodenal ulcers seldom are malignant. Gastric ulcers are frequently malignant ulcers. A very grave responsibility rests upon the physician and the radiographer in following gastric ulcers to watch their healing. If carcinoma of the stomach is going to be cured, surgery must be done early. Early surgery in these cases can only be done by careful evaluation of the clinical and radiographic and gastroscopic findings in cases of gastric ulcer. In all cases of peptic ulcer repeated x-ray examination should be done to follow the healing of the lesion. In our series of 100 patients (Table 1) xray showed 69 duodenal ulcers, 16 gastric ulcers, and 10 patients with combined gastric and duodenal ulcers. Four patients had negative x-rays but these all had excellent histories: one a history of only two weeks' duration, and another had two previous gastric hemorrhages.

## Treatment

It is our feeling that an important factor in therapy of peptic ulcer is the diet. It should be free of stimulating, irritating, and rough foods. We have used a full, bland diet, as we believe that a diet which is too scant or too difficult for the patient to follow will not make for a cooperative patient. On the full, bland diet most patients are able to gain weight. We further believe that the patient should never be hungry, but that he should always have some food in his stomach to combine with the acid gastric juice. This condition is obtained by feeding the patient at least six times during the day and if he has any distress

during the night he must also have one or two night feedings.

For many years we have treated peptic ulcer with the following regimen:

- 1. Bland diet with frequent feedings, at least six times daily, and one or two feedings during the night depending on the severity of night symptoms.
- 2. Extract of belladonna 0.015 three times daily before meals.
- Calcium carbonate 0.60, one hour and two hours after each of the three main meals.
- 4. One teaspoonful of the following powder taken in 1/4 glass of water three hours after the three main meals:

Bismuth subnitrate	30
Light magnesium oxide	20
Prepared chalk	60

Because we have used this method of treatment for so many years, and for purposes of briefness and simplicity, in this discussion we are pleased to call it the "regular treatment," although it is by no means the one which was used most frequently in these patients. The use of belladonna as an antispasmodic is time honored and in our hands we feel that it has definite importance provided it is given to the limits of tolerance. The so-called "regular treatment" was used in 23 patients two of whom were unimproved (Table 2). Diet alone gave benefit eight times and diet and belladonna ten times. These 18 patients were obviously easily controlled and did not need intensive therapy. Calcium carbonate was used as an antacid, 1 Gm. of it having been taken one hour and two hours after meals, with one failure in 27 patients. Calcium carbonate and belladonna were used fifteen times with four failures. Colloidal aluminum hydroxide, 8 cc. in water every two hours, gave no relief of symptoms in four out of seventeen times it was used. Colloidal aluminum hydroxide and belladonna relieved symptoms six times and failed to relieve only once. Magnesium trisilicate 0.60, taken one hour and two hours after meals, relieved symptoms in

3 cases and failed once. When it was used with belladonna there were six improvements and three unimproved patients. The antacid powder previously described was given one teaspoonful in water one hour after meals and gave relief seven times with no failures. When extract of belladonna was added there was one failure and sixteen successful responses.

It has always been our feeling that peptic ulcer is not a disabling disease and that it can usually be best treated while the patient continues at work, if he has been properly educated about his disease. Some ulcers are truly intractable and will not improve, no matter what is done. Seven of our patients during attacks failed to get relief while treated as outpatients. These were hospitalized on ward medicine and all improved. One man became symptom free the moment he was admitted. The other six were treated with either diet alone or diet and antacids. All improved very promptly. Nine of this series of patients went to surgery. Gastroenterostomy was done five times with complete recovery and once, combined with ligation of the gastric and pancreatico-duodenal arteries for severe hemorrhage in a man of 65 years, with death. Resection was done three times. One patient, a man 65 years old, failed to recover.

#### Summary

In a series of 100 cases in the gastrointestinal clinic of the Outpatient Department of the Buffalo General Hospital peptic ulcer of the stomach or duodenum was treated by fourteen different acceptable methods. These methods were used a total of 161 times. There were only nineteen failures in this total number. The patients who suffered the nineteen failures frequently were relieved of their symptoms when the method of therapy was changed.

### Conclusions

1. Any of the acceptable methods of treating

peptic ulcer, if followed intelligently, will give relief in all except the intractable or complicated ulcers.

- 2. Peptic ulcer is a chronic disease characterized by remissions and the patient must be educated about his condition.
- 3. Failures in treatment are due chiefly to the patient's failure to cooperate or the physician's failure to educate or to the use of a method for control of gastric acidity which is too cumbersome or too annoying for the patient to carry out.
- 4. Successful treatment depends upon cooperation of the physician and the patient, and the control of gastric acidity by diet and antacids.

#### Discussion

Dr. John D. Stewart, Buffalo, New York—Peptic ulcer, like thyrotoxicosis, chest disease, neoplasm, and certain other clinical problems, is handled to advantage by a group of physicians of varied interests. Internist, surgeon, radiologist, endoscopist, and laboratory scientist can each make his own contribution in the study and treatment of peptic ulcer, and the doctor as well as the patient profits by such joint management. No doubt both the enthusiasm of the surgeon and the reluctance of the internist will be tempered by free discussion and continued observation. For such reasons, surveys like the present one of material from large teaching hospital are always informative.

As the authors point out, peptic ulcer is a chronic disease subject to remission and recurrence. Results of treatment must be estimated with this point in mind. For example, the surgeon should make it his business to find out how the patient gets along after subtotal gastric resection for ulcer, not only immediately after operation but five years later. Perhaps we should speak in terms of five- or tenyear cures after operation for peptic ulcer, as after operation for cancer.

A statement made in the paper is so important I should like to take the liberty of repeating it. "A very grave responsibility rests upon the physician and radiographer in following gastric ulcers to watch their healing." This can hardly be overemphasized. It has been shown that cancerous ulceration of the stomach may respond symptomatically to a good peptic ulcer regimen such as the authors outlined, and the lesion may improve in radiologic and gastroscopic appearance. The cases of so-called ulcercancer which present the clinical picture of peptic ulcer comprise as many as one-third of the cases of gastric carcinoma in some clinics. The surgeon who has operated upon such patients after competent

gastroenterologists have treated them for peptic ulcer is apt to conclude that gastric ulcer should be considered as largely a surgical lesion. Certainly in the case of gastric ulcer, alertness on the part of the physician and cooperativeness on the part of the patient are essential if serious error is to be avoided.

#### UNTO THE HILLS

Down through the centuries the man of medicine has built a way of life which is embodied in that group of precepts known as professional ethics. Many doctors were attracted to the study of medicine in the first place because they perceived the high standing enjoyed by their family physician. Perhaps without placing it in words they realized as young men that there was nothing higher in this world than devoting oneself to a life of service to one's fellows. In the physician's very attitude of selflessness, he has thereby found himself. And that is the highest reward attained by any man.

Sometimes, in the hurly-burly of the scramble for a living, some doctors have strayed, in various ways, from the narrow path that leads upward. Now and then it is good to learn what others think of us. Such opinions from outside our rather narrow guild tend to stimulate one to once more look unto

the hills from whence cometh our strength.

Recently the Illinois Medical Journal had this

to say:

"One of the best tributes to the medical profession which has come to our attention appeared as an editorial in the *Grant County Herald*, Lancaster, Wisconsin, under date of January 13, 1943. The editor, Mr. A. L. Sherman, in his Remarks to a Young Friend Soon to Graduate in Medicine' presented first a paragraph from the dedication to Underwoods by Robert Louis Stevenson:

"There are men and classes of men that stand above the common herd; the soldier, the sailor, and the shepherd not infrequently; the artist rarely; rarelier still, the clergyman; the physician almost as rule. He is the flower (such as it is) of our

civilization.

"Then follow the complimentary statements to his young friend, which we present in full:

"You are, my young friend, on the brink of your career. Whether or not your career will be great or ordinary depends very much on yourself. You will, I understand, finish medical school this year. After that Uncle Sam will want you for awhile. This will be fine experience. Afterward and in the course of time, you will come back to private life, "put up your shingle," and begin to practice somewhere—maybe in the old home town, which you like so much and where you know everybody and are liked just for yourself. will be a help in some ways and in other ways a handicap-people will find it hard to realize that the little boy they saw at play so short a time ago is now a grown man and a full-fledged physician. Nevertheless, they will have an affection for you because they knew you when you were young.

People are like that.

"But wherever you go to practice you will be among human beings and will have a great opportunity for service. I hope you will be paid and well paid for what you do and I know you will try at all times to earn your money. Nevertheless, the rewards you receive—the great rewards—will not be monetary, but spiritual. The monument you will have in that far distant day when you leave this world and the transfer of the sormer. leave this world will not be stone—it will be some-thing in the memory of the many you served—the men and women, the families, the boys and girls—the people of your clientele. They will re-

member you for what you did for them and will be grateful to you.

"The reason, of course, is because of the peculiar and extraordinary relation which exists between the physician and his patient. You will see people as others rarely see them—when they are ill and despairing and need help desperately. You will not only be a healer of bodies—you will be a healer of souls. You will find the psychic side of your ministration of importance equal to the physical, ofttimes more so.

"'In ministering to human beings you will find them with the bars down and without glamour there will be none of the little ordinary masks and pretenses we all wear to meet the world. Yet even though the fellow-man you serve may be helpless, even undignified, you will find something noble and livable about him, something that transcends and is beyond any definition of the physical, something above the anatomical and that defies material analysis. He is a human being.

"'If you did not feel like this you would be no true physician and would be wasting your time as a doctor. Nor would you be much good to the

world.

"I remember, many years ago, hearing a young medico tell me he was "out for the money." The money was there to be made and he was going to "get his." "I would cut a man's head off for five dollars, if he paid me for it," this young scoundrel was fond of declaiming. His crass attitude horrified me and I read with pleasure a few years later that he had been prosecuted and punished as a particularly venal sort of quack. If ever a man's rotten and cynical philosophy caught up with him, this was a striking example.

"In conclusion let me say that I have kicked around this world for over half a century. I have always studied people, remembering the advice of the sage that "the proper study of mankind is man." I can say with Stevenson, that no calling in the world has a higher opportunity for human service than the true physician. This is not to say that all the doctors one meets are true and great, or that many of them are anything else but mediocre. But when you meet a good one—a great humanist as well as a great physician-how

his light does shine!

"In far flight and at long last, I see you—in mind's eye. You will be wearing spectacles, be-cause your once keen sight will be dim. Your shoulders will be rounded and your step slow, due to the advance of the years. Your hands will be gnarled—instead of white and supple as they are now. And maybe your breath will be a bit wheezy We will say nothing of wrinkles, of which you will doubtless have plenty. All these, and the wear inside, will be accolades of honor. You will have spent yourself in human service-which I can assure you is the greatest way possible to spend a life. And you will be tranquil, happy—not caring much what happens to yourself-you will have done so much for others.

" 'So you're going to be a doctor?

"Well, go in and win, my boy—and may God bless and keep you!"—Editorial in Southwestern

3 cases and failed once. When it was used with belladonna there were six improvements and three unimproved patients. The antacid powder previously described was given one teaspoonful in water one hour after meals and gave relief seven times with no failures. When extract of belladonna was added there was one failure and sixteen successful responses.

It has always been our feeling that peptic ulcer is not a disabling disease and that it can usually be best treated while the patient continues at work, if he has been properly educated about his disease. Some ulcers are truly intractable and will not improve, no matter what is done. Seven of our patients during attacks failed to get relief while treated as outpatients. These were hospitalized on ward medicine and all improved. One man became symptom free the moment he was admitted. The other six were treated with either diet alone or diet and antacids. All improved very promptly. Nine of this series of patients went to surgery. Gastroenterostomy was done five times with complete recovery and once, combined with ligation of the gastric and pancreatico-duodenal arteries for severe hemorrhage in a man of 65 years, with death. Resection was done three times. One patient, a man 65 years old, failed to recover.

#### Summary

In a series of 100 cases in the gastrointestinal clinic of the Outpatient Department of the Buffalo General Hospital peptic ulcer of the stomach or duodenum was treated by fourteen different acceptable methods. These methods were used a total of 161 times. There were only nineteen failures in this total number. The patients who suffered the nineteen failures frequently were relieved of their symptoms when the method of therapy was changed.

#### Conclusions

1. Any of the acceptable methods of treating

peptic ulcer, if followed intelligently, will give relief in all except the intractable or complicated ulcers.

- 2. Peptic ulcer is a chronic disease characterized by remissions and the patient must be educated about his condition.
- 3. Failures in treatment are due chiefly to the patient's failure to cooperate or the physician's failure to educate or to the use of a method for control of gastric acidity which is too cumbersome or too annoying for the patient to carry out.
- 4. Successful treatment depends upon cooperation of the physician and the patient, and the control of gastric acidity by diet and antacids.

#### Discussion

Dr. John D. Stewart, Buffalo, New York—Peptic ulcer, like thyrotoxicosis, chest disease, neoplasm, and certain other clinical problems, is handled to advantage by a group of physicians of varied interests. Internist, surgeon, radiologist, endoscopist, and laboratory scientist can each make his own contribution in the study and treatment of peptic ulcer, and the doctor as well as the patient profits by such joint management. No doubt both the enthusiasm of the surgeon and the reluctance of the internist will be tempered by free discussion and continued observation. For such reasons, surveys like the present one of material from large teaching hospital are always informative.

As the authors point out, peptic ulcer is a chronic disease subject to remission and recurrence. Results of treatment must be estimated with this point in mind. For example, the surgeon should make it his business to find out how the patient gets along after subtotal gastric resection for ulcer, not only immediately after operation but five years later. Perhaps we should speak in terms of five- or tenyear cures after operation for peptic ulcer, as after operation for energy.

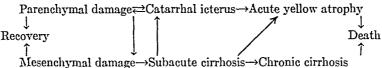

operation for cancer.

A statement made in the paper is so important I should like to take the liberty of repeating it. "A very grave responsibility rests upon the physician and radiographer in following gastric ulcers to watch their healing." This can hardly be overemphasized. It has been shown that cancerous ulceration of the stomach may respond symptomatically to a good peptic ulcer regimen such as the authors outlined, and the lesion may improve in radiologic and gastroscopic appearance. The cases of so-called ulcercancer which present the clinical picture of peptic ulcer comprise as many as one-third of the cases of gastric carcinoma in some clinics. The surgeon who has operated upon such patients after competent

usually either complete repair (recovery ad integrum), or complete destruction (acute yellow atrophy). With the additional involvement of the mesenchyme elements repair is demonstrated by connective tissue formation and all the evidence of the elements of an inflammatory process, namely, new capillaries, fibrin, leukocytes, and fibroblasts. Such cases may eventually go into the stage of subchronic or even chronic cirrhosis of the liver. Combined forms and transitions from one type of involvement to the other are also encountered.

depends upon the quantity of harmful substance and upon the ability of the organ or of the individual cells to resist the invader.

Additional causative factors are micro-organisms like the paratyphoid, including the Salmon ella group, the colon bacillus, and the staphylococcus, which may be imbibed with decomposed food. Decomposed food in itself may cause hepatocellular catarrhal interus by its toxic effect. As a rule the bacteria cannot be isolated, although Eppinger reported the presence of paratyphoid B in the parenchyma of the liver

Hepatocellular icterus is classified pathologically as follows:

- Noninflammatory
   Parenchymatous—acute or subacute catarrhal icterus
- 2. Inflammatory Postvaccinal hepatitis
- 3. Rarer changes causing jaundice
  Periacinous
  Subacute or chronic cirrhosis of the liver
  Icterus gravis
  Acute yellow atrophy
  Carcinoma of the liver
  Stones in the liver
  Telangiectasis of the liver
  Jaundice due to drug, food, or chemical
  poisoning

## Hepatocellular Catarrhal Jaundice

Hepatocellular catarrhal jaundice is not confined to either sex. It occurs usually during youth or maturity, but the extreme ages are not immune. The source of the causative toxic element is not definitely known. Certain chemicals taken internally produce changes in the parenchyma of the liver cells, such as atophan, salvarsan, neosalvarsan, large doses of chloroform, arsenic, more rarely bismuth, the specific toxins of the spirocheta pallida, phenylhydrazine (advocated by Eppinger as a therapeutic agent in polycythemia vera), and phosphorus taken internally with suicidal intent. Among causative chemicals contacted externally through occupation are tetrachlorathone, which is used in the manufacture of aeroplanes, paratoluenediamine, used in hair dye, phosphorus fumes inhaled by workers in match factories, trinitrophosphorus, and trinitrotoluenediamine, which is used in making x-ray screens and which occasionally causes mild jaundice (Henche). As in any damaging process of the body, the result of one patient who died of this disease. The causative bacteria are usually too rapidly destroyed in the liver for any of them to be detected later.

Some observers deny that food poisoning can be a causative factor by pointing out that one member of a family may eat the food and develop icterus while others can eat the same food without becoming icteric. However, toxins are not equally distributed throughout the bulk of food; furthermore, the quantity eaten varies with different members of the family, even to those who eat very little because of their keen sensitivity to the odor of contaminated food. Also, some individuals have a greater inherent constitutional resistance of the body at large and of the hepatocellular elements specifically so that, regardless of the quantity of food eaten, they do not develop jaundice.

The constitutional factor is demonstrated by the occurrence of icterus in more than one member of the same family. We had occasion to observe two brothers who were afflicted with jaundice. In one, the disease ran a normal course of six weeks with complete recovery. A year later, however, the jaundice recurred and terminated fatally as acute yellow atrophy. His brother developed hepatocellular catarrhal icterus and made a perfect recovery without recurrence. Acute outbreaks of hepatocellular catarrhal icterus have occurred that are not traceable to food or to any known cause. One epidemic of this nature was reported by Blumer; he termed the condition acute infectious jaundice.

Symptomatology.—The onset is that of a gastrointestinal upset of varying severity. Characteristically, within a few hours or even an hour after a certain meal, the patient experiences nausea, epigastric distress, sometimes vomiting which may be intractable for hours, and fre-

Hepatocellular Catarahal Icterus and Hepatitis Following the Use of Yellow Fever Vaccine: Clinicopathologic Comparisons

I. W. Held, M.D.,\* and A. Allen Goldbloom, M.D., New York City

CTERUS, although an easily recognized symptom, offers great difficulty in diagnostic interpretation. Literally, icterus means staining of the tissues with the coloring matter of bile-namely, bilirubin-and, very rarely, with biliverdin. Bilirubin does not stain all tissues equally, and certain tissues, such as cartilage, cerebrospinal fluid, and cornea do not stain at all; the infundibulum cerebri stains with bile only in the grave form of icterus neonatorum. It is also characteristic of icterus that it deeply stains excretions and leaves the secretions free. Hence, urine, feces, tears, and perspiration are deeply stained, but gastric secretions and the spinal fluid are not stained. The gravity of the disease is determined by the underlying pathologic changes in the liver and the functional disturbance caused by such pathology, rather than by the degree of staining of tissues or duration of the icterus.

Rosenthal<sup>1</sup> has stated that elastic tissue does not stain with bilirubin. Although fat, an elastic tissue, is yellowish in jaundice, the stain can be washed away with water, indicating a covering of the surface rather than an imbibition of the bilirubin. Jaundice appears first on the sclerae, next on the face and trunk of the body. The extremities are never as deeply stained as the rest of the body. When jaundice begins, the bilirubin is in higher concentration in the blood than is evidenced on the body surface. As it subsides, the bilirubin diminishes from the blood first and from the sclerae last.

Although jaundice is the leading symptom, many other symptoms, as well as the outcome, will depend on the damage to the polygonal cells and the retention in the blood of other constituents of bile, such as bile acids; they will depend also on a disturbance in cholesterol and water metabolism and a disturbance in inorganic electrolytes (sodium, phosphate, sulfate, potassium, calcium, and magnesium). The so-called "emotional icterus" is undoubtedly due to an imbalance in the vegetative nervous system, which includes electrolytic imbalance.

According to frequency, ieterus may be caused by:

- 1. Obstruction of the flow of bile in the ducts, which is called regurgitation icterus (Rich).
- \* Attending Physician, Beth Israel Hospital, New York City; formerly, clinical professor of medicine, New York University College of Medicine.

- 2. A disease process in the liver cells which brings about a disturbance in the secretion of bile and in the passage of bile from the cells through the canaliculi into the bile duets, termed absorption icterus.
- 3. Hemolysis, overproducing bilirubin so that a great part goes into the blood, thence into the tissues, which is known as retention icterus.

Our discussion will be confined to the type of icterus that is due to a disturbance in the polygonal cells of the liver, the so-called absorption icterus.

Absorption icterus is today recognized a due to changes in the parenchyma of the liver and is therefore truly hepatocellular icterus. I is unrelated to catarrhal duodenitis; neither i it due to a plug obstructing the sphincter o Oddi, as was suggested by Virchow. The firs pathologic proof of this fact was provided by Eppinger,2 who during World War I was afforder the opportunity of performing autopsies upo the bodies of three soldiers killed in battle at time when they were still icteric. The livers of these soldiers were found to be enlarged, th polygonal cells were distorted and staine poorly, the nuclei of the cells were deforme and likewise stained poorly, and the norma arrangement of cells was slightly disturbed wit the central vein somewhat eccentric. Som nuclear detritus was seen between the cells The lymph vessels appeared dilated and wer in close proximity to the blood capillaries There was no round cell infiltration and n other evidence of an active inflammatory process These findings were later confirmed by Klemp erer, Killian, and Heyd3 in this country.

The names "hepatitis" and "hepatosis" hav been applied to this disease by various authors. However, as has just been stated, the pathologi changes are confined to the polygonal cells an are not inflammatory in character. Therefore hepatitis is inaccurate, and hepatosis is to vague. The lesion being catarrhal, the nam hepatocellular catarrhal icterus, as was suggested by us in a previous publication, seems to be most appropriate.

Rössle<sup>5</sup> made an important contribution when the demonstrated that damage of the parenchymacells of the liver may be accompanied by in volvement of the mesenchyme cells. He found that in parenchymal involvement there was

270

Fig. 1.—Catarrhal icterus. Liver with fresh central necrosis with inflammatory changes in the periportal region.

This is rare in the benign type of hepatocellular icterus, but is often present in the severe type, particularly where subacute yellow atrophy results.

During the stage of recession, the bilirubin of the blood gradually diminishes, urobilin and urobilinogen in the urine become less marked; icterus disappears from the extremities, but remains quite marked on the body. The sclerae continue to be tinged, sometimes remaining so for several weeks after all subjective and objective symptoms have abated. The symptoms begin to disappear in the fifth week; the disease usually terminates in six weeks, followed by improvement of appetite and increase in weight. However, cases have been encountered of two to three weeks' duration, others of two to four months'. In the latter event, it is reasonable to assume additional periacinous involvement (see Fig. 1) and mesenchymal involvement, but in completely reversible form. This is in contradistinction to cases of mesenchyme change eventually progressing to subacute or chronic cirrhosis of the liver. In the reversible type, with the disappearance of the symptoms the liver returns to normal size; otherwise the enlargement of the liver and spleen remains permanent. Occasionally, a case of protracted jaundice may be entirely reversible, as illustrated by that of a 66-year-old female, with typical symptoms of catarrhal icterus, only the liver being enlarged. Icterus deepened and per-

sisted for six months. Because of advanced age and liver enlargement, a diagnosis of metastatic carcinoma of the liver, primary lesion undetermined, was made. However, after six months, the patient began to improve and recovered completely.

*Prognosis.*—The prognosis is very favorable in the vast majority of cases. Rarely, after the disease has run a benign course for three or four weeks, a turn for the worse suddenly-takes place, the patient becomes confused and drowsy, the temperature is elevated, there is nausea and vomiting, deepening of jaundice, then coma and death. When the liver cannot be palpated one immediately suspects acute yellow atrophy of the liver. We recently had a case at the Beth Israel Hospital of a 14-year-old boy who had all the clinical evidence of benign type of hepatocellular icterus except that jaundice failed to subside. When he was admitted to the hospital at the end of the fourth month, the only grave findings were a very high bilirubin concentration in the blood and the fact that the liver could not be palpated. A note was made of the possibility of subacute yellow atrophy. On the sixth day in the hospital he suddenly complained of drowsiness, developed ecchymotic spots over the trunk, and died twelve hours later in coma. Autopsy by Dr. Alfred Plaut showed diffuse areas of complete destruction of the polygonal cells of the liver, and as in most of these cases, hemorrhagic areas in the duodenum and jejunum.

# Hepatitis Following the Use of Yellow Fever Vaccine\*

The recent outbreak of jaundice among our armed forces indicates under what treacherous circumstances hepatocellular disease with resulting protracted jaundice may occur. All observers have agreed that these cases clinically resemble the hepatocellular catarrhal icterus group. Fortunately, with the exception of a small percentage, the disease terminated favorably. 125 cases per month were reported in the first two months of this year. The comparatively small percentage of fatalities, in the face of the large number of affected individuals, amounted to about seventy deaths. The problem has been a major concern of Army authorities, since the health of the Army and all its constituents is vitally important to a well-coordinated war effort.

From reports of a number of postmortem studies it became evident that this affection is definitely inflammatory, in contradistinction to

<sup>\*</sup> Findlay, G. M., and MacCallum, F. O.: Trans. Roy. Soc. Trop. Med. & Hyg. 31: 297-308 (1937).

quently diarrhea. Pain is, as a rule, absent; however, in some cases it may be severe, radiating to the spine, right hypochondrium, and right shoulder, requiring a narcotic. When jaundice appears in such cases, it may be difficult to differentiate the disease from obstructive The following points are aids in the differential diagnosis. In hepatocellular catarrhal jaundice, icterus begins on the sixth to ninth day, and spreads very rapidly, whereas in the obstructive type, jaundice starts on the second or third day after the attack of pain, and advances very gradually. If obstructive jaundice occurs in one in whom the gallbladder had previously been removed, the icterus may begin within the first twelve hours after the attack of pain. On the other hand, progressive jaundice which is the result of pressure on the biliary ducts from without—by carcinoma of the head of the pancreas or adenoma of the papilla Vateriis usually preceded by gastrointestinal symptoms for many weeks.

It is important to point out that after the pain subsides, in hepatocellular catarrhal icterus, it does not recur, the remaining course of the disease being characterized only by the subjective symptoms of distress in the epigastric region or right hypochondrium. The finding of a considerable increase of urobilin and urobilinogen in the urine should warn the physician of a beginning catarrhal icterus, rather than an ordinary gastrointestinal upset. In contradistinction to acute gastro-enteritis, the patient's temperature is usually not elevated, although in children it may rise to 102 to 104 F, for several days, due to the hypersensitivity of the thermic center, and not to infection. Also, vomiting, which occurs in gastro-enteritis, does not persist in catarrhal icterus. The tongue is heavily coated, the patient frequently has severe headaches, and feels physically exhausted. This preicteric state may last six to nine days, after which a yellowish coloring of the eyes and a yellowish tinge of the face and body are noticed. This marks the beginning of the phase of true icterus.

The icteric phase has been divided into three stages—dry, catarrhal, and recessional (Held, Kramer, and Goldbloom<sup>4</sup>), analogous to catarrh of any other part of the body, such as of the nasopharyngeal region. In the stage of dryness it is our concept that the secretion of bile is markedly retarded in the polygonal cells of the liver. Due to the disturbed function of the liver cells, sufficient amounts of bile and bile pigments pass into the blood and thence into the tissues to give a moderate icteric tinge to the sclerae, but with a marked increase of the direct bilirubin of the blood, also of urobilin and uro-

bilinogen in the blood, urine, and feces. The liver is usually moderately enlarged and often tender to palpation, and in some instances particularly in children, the spleen is also enlarged.

During the catarrhal stage there is an overproduction (or running) of bile in the liver cells, large quantities of the bile entering the blood so that the bilirubin content rises to 6 to 12 mg. The icteric index increases correor more. spondingly, the stool becomes acholic, and the urine is saturated with bile. Urobilin and urobilinogen during the catarrhal stage may temporarily disappear, arousing suspicion of complete obstruction. The liver may become considerably enlarged, due to the stretching of the capsule of Glisson, with pain in the hepatic region either spontaneously or elicited on pressure. The spleen may be somewhat enlarged. It is noteworthy that in obstructive jaundice the spleen is never enlarged. The subjective symptoms of the second stage are drowsiness, marked loss of appetite, slow pulse, sometimes even 40 to 50 per minute, simulating heart block, which is vagal in origin. The pulse rate can easily be increased by the administration of atropine.

After jaundice has appeared the gastrointestinal symptoms become milder. The urine contains albumin and many hyalin and granular casts. This may be attributed to a mild nephrosis which is reversible, disappearing entirely when the patient recovers. Usually there is no vomiting, but nausea persists and the appetite is poor with an aversion to food and consequent loss of weight. Pruritis is a marked symptom in hepatocellular jaundice and is especially annoying on the covered areas of the body, the patient preferring to sleep uncovered in an attempt to alleviate the itching sensation. An interesting phenomenon during this stage is a considerable diminution in the urinary output, verified by the Volhard water test. The patient is given 1,000 cc. of sweetened tea on a fasting stomach. Normally about 80 per cent of the quantity should be eliminated within forty-five to ninety minutes. If there is hepatocellular damage it may not be eliminated before three or more hours have passed. However, if the patient has diarrhea and is losing water from the intestines, the test is of no value. When improvement begins, the test not only becomes negative, but the patient may eliminate more than the intake-probably most of the water that has been retained in the tissues throughout the disease, although there is no external evidence of edema. In some instances the water metabolism is so disturbed that ascites, occasionally to a marked degree, may be present

esters. In severer cases the cholesterol-ester concentration may be considerably lowered so that acute yellow atrophy is suspected, but the cholesterol-ester returns to normal after a few days. The sedimentation rate may be slightly lowered. The duodenal contents show the presence of both bile and urobilin, indicating that we are not dealing with obstructive jaundice. Microscopically, a few pus cells, bilirubin crystals, and even cholesterol crystals may be found.

Pathology.—The earliest lesions consist of frank necrosis of liver cells in the central parts of the lobules. There are no inclusion bodies at any stage. Lesions differ distinctly from those of yellow fever. Fatty changes are not a conspicuous feature. Destruction of liver tissue and the removal of the debris is invariably accompanied by inflammatory reactions, and the term "hepatitis" is therefore proper. Investigations have shown changes in organs other than the liver. Marked edema, often accompanied by intense inflammation of the gastrointestinal tract, has been noted. The changes are usually pronounced in the cecum. The kidneys may present the picture commonly known as bile nephrosis. "Cholemic nephrosis" and acute or subacute splenic tumor are usually present. Hemorrhages, often extensive, in serous and mucous membranes are common. The central nervous system shows changes similar to those found in other severe toxic metabolic disturbances

### Functional Tests

The liver, seat of numerous functions, has been subjected to the most exhaustive laboratory studies in order to establish tests which can determine early pathologic changes in the different parts of the liver, such as ducts, Kupffer-stellate cells, epithelial cells, etc. One must agree with H. Eppinger's statement of many years ago, that despite the most diligent search for functional tests, their efficacy at the bedside is still greatly disappointing. The same author pointed out that many a young clinical assistant at the hospital is encouraged to search for functional tests, first by means of animal experiments and then on humans. The animal experiments give him a great deal of encouragement, but when he applies the test to the human, his disappointment begins. This is to be expected, in view of the fact that the liver, like the pancreas, has such an immense reserve and such extraordinary regenerative power that only when it is seriously, acutely diseased is there marked disturbance of its vital functions. In previous publications we pointed out that the more indispensable the organ to existence, the more compensatory mechanism does it possess. Thus, although seriously damaged by a pathologic process, the liver can respond to all the metabolic demands of the body for a long time. Animal experiments have shown that with only 15 per cent of the liver intact all functions can go on undisturbed. On the other hand, less vital organs, particularly those that are not indispensable, such as tonsils, nails, appendix, or prostate, if only moderately diseased, can cause disturbed function to such a degree that the removal of the affected organ or part of the organ becomes obligatory for the protection of the body at large. Another important factor determining the degree of disturbed function is the stage of the disease. An important organ, such as liver, kidneys, or lungs, when acutely diseased, will have disturbance in function out of proportion to the degree of pathology; but when chronically diseased the pathologic changes are entirely out of proportion to their disturbed function Nevertheless, despite all these shortcomings, in cases of liver damage with jaundice, the scientific approach to the study of functional disturbances of this vital organ is sufficiently interesting and often of such diagnostic and prognostic value as to justify the utilization of the known tests. If they are of assistance in only a small number of cases, all effort expended in their application is well compensated. We cannot sufficiently overemphasize here, as in diseases of all organs and in all stages of pathologic involvement, the primary diagnostic importance of careful physical examination and notation of clinical symptoms. Functional laboratory tests serve only as confirmatory evidence. Extensive bedside experience has taught that if laboratory examination fails to agree with the clinical concept, the latter is more frequently correct.

275

In this discussion it is not our intention to describe these functional tests; the procedures are contained in all laboratory manuals of clinical pathology. We rather aim to point out their direct value and their reliability from a prognostic and diagnostic viewpoint.

Water Test.—In prognosis the simple water test mentioned previously is of great value. As long as the elimination of the fluid is markedly retarded the disease is still at its height; and in those protracted cases of jaundice where the test gives low results and the natural urinary output is also very diminished, one is still in doubt as to whether such a patient may not develop a subacute or chronic cirrhosis of the liver, or even acute atrophy. Although the water test is very simple, it is remarkable to note how infrequently it has been employed, and it deserves greater emphasis.

Bilirubin Content in the Blood.-This is an

hepatocellular catarrhal icterus. It has therefore rightfully been named hepatitis.

Etiology.—John P. Fox8 and his coworkers studied 494 cases of postvaccinal jaundice, with twenty-four deaths. Their findings prove that pathologically they were dealing with definite inflammatory changes of the liver parenchyma. The liver was usually smaller, greenish, or yellow-red, there were areas of granulation, and in some parts small nodular areas. The left lobe was more involved than the right. Microscopically the cells showed extensive degeneration and necrosis. Secondary changes of a reparative nature were observed, consisting of hyperplasia of peripheral cells and of bile ducts and proliferation of fibrous tissue. In some cases the lesions resembled what Boyd9 described as infectious biliary cirrhosis, but differed in that it was associated with a marked degree of portal cirrhosis. They found hyperemia as well as free hemorrhages in the small intestines, as did other authors. These authors feel that the disease was caused by certain lots of vaccine. They also feel that there was some second factor. It is our concept that the second factor was either constitutional or nutritional.

Results of investigations to date have been negative as far as a demonstration of a transmissible agent is concerned. The outbreak of jaundice in the Army is not Weil's disease, leptospiral infection, bacterial infection, infectious mononucleosis; it is not yellow fever or a modified form of yellow fever. Yellow fever virus has not been recovered from any material, that is, blood, bile, urine, liver, etc., of jaundiced patients. Extensive research for the cause has thus far shown that the most likely underlying factor is a virus in the vaccine for yellow fever, hence the name, "postvaccinal" hepatitis (Circular 95 from the Surgeon General's office, August 31, 1942). The decision to continue vaccination is most praiseworthy. Although possible ensuing jaundice is most unpleasant, the risk of exposure to yellow fever is far greater.

The conclusion of the Surgeon General's office concerning the outbreak of this type of jaundice following the administration of certain lots of yellow fever vaccine is that it is not contagious, and hence does not constitute a danger to the public health.

As in hepatocellular catarrhal jaundice, the question is posed, why do the vast majority of vaccinated subjects escape hepatitis? Here too the constitutional status, vague as it may be, must be taken into consideration. Also, variations in the general state of nutrition of the vaccinated subject are important factors. Through studies in nutrition, such as those of Joliffe and Rich on vitamin B, and the extensive

chemical investigations on the relation of choline to the susceptibility of the liver to disease (Vincent du Vigneaud, of Cornell University, on the significance of labile methyl groups in the diet and their relation to transmethylation), it is hoped that some uniformity of diet may eventually be the protective and prophylactic agent against liver affections.

Rivers, of the Rockefeller Institute, among other investigators, has pointed out that the virus, as such, is responsible for a number of infections, such as influenza, poliomyelitis, herpes zoster, and some forms of encephalitis. The severity of the disease or the fatal outcome often depends on a superimposed infection, such as by streptococcus or pneumococcus. One may therefore venture the statement that postvaccinal hepatitis does not run a fatal course and the disease is even entirely reversible, since as a rule there is no superimposed infection; also, that as long as the functional damage to the liver is not severe, recovery takes place.

Symptomatology.—Unlike hepatocellular catarrhal icterus, where gastrointestinal symptoms begin several hours, or at most one to two days after the ingestion of a certain food, in postvaccinal jaundice many weeks or months may elapse between yellow fever vaccination and the onset of gastrointestinal symptoms. As a rule, they vary in severity and are considerably milder than in catarrhal icterus. Jaundice, which varies in intensity, develops more slowly. The prodromal symptoms may also consist of fatigue, lassitude, and anorexia. In some cases nausea, diarrhea, and vomiting may be present. The temperature is usually normal or slightly elevated. Even during this preicteric state physical examination may disclose moderate enlargement of the liver, which is tender in 20 per cent of the cases. The spleen may be moderately enlarged. Joint pain and urticaria are present in about 20 per cent of the cases, suggesting that the condition may be allergic in origin. However, all other manifestations of allergy, such as eosinophilia, were absent. The diminution of urinary output is considerable and becomes very marked at the height of the disease. In addition to bile pigment, the urine also contains albumin and casts, and there is an increase in amino acids. The stool is usually acholic; occasionally bile and bile acids are present. At the height of jaundice the bilirubin in the blood reaches a high though variable level. As the jaundice subsides, the bilirubin likewise diminishes so rapidly that it may become entirely normal before the last vestige of jaundice Although the total has left the face and chest. cholesterol is lowered there is no disturbance in the relation between cholesterol and cholesterolreblady 1, 1911

show the advancing pathology of the liver before acute yellow atrophy, and the advanced stage of acute yellow atrophy.

Hippuric Acid Test (Quick<sup>21</sup>).—According to many authors, if the hippuric acid test is positive it is an indication of hepatocellular damage. The test is based on the detoxifying activity of the liver cells on benzoic acid.

Serum Phosphalase Test.—This test aids in differentiating between obstructive and non-obstructive jaundice. However, some authors have found that the phosphatase is acutely disturbed in both types of jaundice. It is also elevated in a large number of cases of neoplastic involvement of the liver.

Hanger<sup>22</sup> Flocculation Test.—The index of disturbance of the liver parenchyma is determined by this test. With normal human serums the emulsion of cephalin-cholesterol antigen remains as a stable homogeneous suspension, but with serums from patients with diffuse hepatitis the lipoid material tends to flocculate and is precipitated to the bottom of the tube. Notation is made at the end of twenty-four and forty-eight hours as to the amount of flocculation and precipitation that has taken place.

Sodium d-Lactate Tolerance Test.<sup>23</sup>—This test for hepatic function depends on the ability of normally functioning hepatic cells to convert blood d-lactate into glycogen. The dextrorotatory form of lactic acid is the physiologically occurring isomer encountered as an intermediary product in the carbohydrate cycle involving muscle and liver. Recently C. Cohn<sup>24</sup> confirmed these findings and stated that this is an important test in differentiating between hepatocellular and obstructive jaundice. Retention of 5 mg. of the d-lactate per 100 cc. or more of the injected lactate, after one-half hour, indicates hepatocellular injury.

## Treatment

Pre-Icteric Stage. - The same method is applied to cases of catarrhal icterus and postvaccinal hepatitis. During the prodromal stage, when the gastrointestinal symptoms are in the foreground, particularly if vomiting and diarrhea are persistent, dehydration is likely to result. The intravenous administration of 10 per cent glucose in normal saline, at least 500 cc. twice daily, is an effective prophylactic measure. In rare cases of protracted vomiting the slow continuous intravenous method should take preference, and in protracted diarrhea, enemas of normal saline solution. It is our firm conviction that active treatment in the early stage may serve to reduce the severity of jaundice and shorten the course of the disease. Intravenous glucose infusion stores glycogen in the liver and thus may prevent serious damage to the liver cells.

Among large aggregations of men, such as in Army camps, periodic outbreaks of gastro-enteritis are inevitable, and symptoms are sometimes severe enough to threaten dehydration. When such outbreaks occur, dehydration can be prevented by the previously mentioned methods. Should this gastro-enteritis prove to be a forerunner of jaundice, treatment will have served a double purpose—the immediate combatting of dehydration, and the lessening of severity and duration of jaundice.

If gastric symptoms are accompanied by a marked increase of urobilin and urobilinogen, suspension of ensuing jaundice is more definite.

When vomiting persists, either iced or sweetened hot tea, depending on the patient's preference, should be given. Occasionally aspiration of gastric contents through a Levin tube—passed preferably through the nose—and lavage of the stomach with normal saline or a mild alkaline solution may become necessary.

Should nause and vomiting persist despite treatment, further measures consist of small peroral doses of 0.006 Gm. of cocain hydrochloride or 0.25 Gm. of anesthesin.

When constination as well as vomiting is in the foreground, small doses of calomel-0.03 Gm. every half-hour until ten tablets are takenfollowed by 6 ounces of citrate of magnesia are effective. As long as the patient feels exhausted and takes very little food, it is most advisable that he remain in bed. After a day or two, when vomiting has stopped, feeding should begin with peptonized milk, milk mixed with thin barley, tea with milk, sweetened fruit juices, baked apple, or apple sauce. As improvement continues the diet is increased with toasted bread, proteins such as chicken, fish, and cottage cheese. Proteins should not be withheld, since the liver is greatly dependent on their intake, particularly the amino acids, as indicated by the work of Ravdin,25 who advocates the use of amino acids intravenously in order to protect the liver cells.

Icteric Stage.—If the patient has no elevation of temperature he may be out of bed for the greater part of the day, and even out of doors. He should not be permitted any work, either physical or mental, the latter being more harmful. The bad taste in the mouth and heavily coated tongue require hygienic attention to mouth and teeth. The skin, which usually becomes dry and scaly, should be sponged twice daily with 2 per cent menthol in alcohol, which will allay or alleviate itching.

Diet is the most important feature of the management, as has been substantiated by ex-

important determination. Whether we test for bilirubin directly or indirectly depends on whether we are dealing with the hemolytic, absorption, or regurgitation icterus. It is vitally important to watch during the course of the disease to see whether the bilirubin in the blood is on the increase, and when it begins to diminish. If the bilirubin climbs continuously higher in the fifth or sixth week, prognosis becomes alarming and the outcome doubtful. The reverse is true if the bilirubin declines during the same period. The identical significance is attributed to the icteric index.

Icteric Index.—The icteric index, as modified by Alice Bernheim, 10 is a simpler test than bilirubin determination, and can well replace the latter. The normal index is 5. The zone of latent jaundice lies between 5 and 15. When it reaches 15 or 16, jaundice becomes evident. 115 was the highest index reported by Bernheim.

Bilirubin Elimination Test.—This test (Eilbott and Bergmann)<sup>11</sup> should be used only where definitely indicated, because the material is extremely expensive. One mg. of bilirubin per kilogram of body weight is injected into the blood and the length of time required for its elimination from the blood is determined. Normally the entire quantity disappears from the blood in two to four hours. In disease of the ducts as well as liver cells it may be retained in the blood for days.

Urobilin and Urobilinogen.—These substances in the stool and urine serve to differentiate the obstructive (regurgitation) type from the hepatocellular jaundice (absorption type). If urobilin is temporarily absent in the urine and feces the examination of the duodenal contents may be necessary. In complete obstructive jaundice urobilin and urobilinogen are absent from the duodenal contents, whereas in hepatocellular jaundice they are always found, even if moderately diminished.

Determination of Cholesterol and Cholesterol-Ester in the Blood.—This is another important test, as introduced by Thannhauser and Schaber 12 and carefully carried out in this country by E. Z. Epstein and E. B. Greenspan. 13 During wartime, because of the shortage of alcohol, the test presents an economic problem. It should therefore not be used too freely or routinely, but should be reserved for those cases that present difficulty as to the differential diagnosis between obstructive or hepatocellular catarrhal jaundice. In the former, the cholesterol is markedly increased, and the relation between cholesterol and cholesterol-ester remains undisturbed; in the latter the total cholesterol is diminished and the cholesterol-ester, which is normally present in twice the quantity of free

cholesterol, diminishes and may eventually disappear from the blood—a very ominous sign that the liver cells are being completely destroyed. Fortunately this is rare.

Bromsulfalein Test.—This test devised by Rosenthal<sup>14</sup> is very useful. 20-50 per cent of the dye is normally found in the serum five minutes after injection, and the serum is entirely free after thirty minutes. In cases of hepatic disease the serum will retain the dye varying from 3-99 per cent in thirty minutes.

Rose Bengal Test. 15—Gives retention of more than 50 per cent of the dye (10 cc. of 1 per cent solution of rose bengal) after eight minutes in the presence of hepatic damage.

Quick Prothrombin Determination. 16.—The concentration of prothrombin in the blood is a direct clue as to hemorrhagic diathesis, especially in obstructive jaundice. Since it is known that prothrombin is formed in the liver, deficiency of prothrombin is a definite indication of liver cell damage, and therefore treatment with vitamin K is indicated.

Galactose Tolerance (Richard Bauer<sup>11</sup>) and Levulose (H. Strauss<sup>18</sup>) Tests.—The former test is positive for true hepatocellular disease and the latter is indicative of disease of the biliary ducts; they are simple procedures. In the acute stage of jaundice these tests are of great value, but they are often negative in the chronic stage.

Blood Urea.—In protracted cases of jaundice the concentration of blood urea must be carefully observed. Often coaffection of the kidneys may cause increase of urea in the blood. However, when the urea begins to diminish markedly serious hepatocellular damage is indicated. In acute yellow atrophy, the urea may entirely disappear from the blood.

Protein Metabolism.—Addis19 showed that the liver contains a labile reserve of protein which is readily depleted during fasting and restored when protein is fed. Liver disease depresses regeneration of the plasma proteins because of the impaired ability of the liver to utilize protein normally. The albumin fraction in liver disease is affected more than the globulin, so that the albumin-globulin ratio is inverted, especially in hepatic cirrhosis. Marked inversion of the albumin-globulin ratio in acute hepatocellular disease indicates that the patient should receive sufficient protein in his diet. Although the feeding of protein does not increase the protein in the blood, as in nephrosis, it does serve to prevent further damage to the liver and aids in the prevention of edema and ascites.

Leucine and Tyrosine Tests.—Particularly by the simplified method of Lichtman, 20 these tests

#### CLINICAL RESEARCH MEETING TO BE HELD BY THE NEW YORK ACADEMY OF MEDICINE

The New York Academy of Medicine will hold a meeting in the first week of April to provide a forum in which research workers of New York City and vicinity may present results of original research in clinical medicine.

This meeting is being arranged by the Committee on Medical Education of the Academy in view of the dearth of meetings of national medical societies before which research work has usually been presented.

Presentations will be limited to twelve minutes. A brief period of free discussion will follow each presentation. The publication of presentations is not a necessary condition but the Academy plans to publish in the Bulletin abstracts of presentations if the author so desires. The fact that material has in substance or in part been presented elsewhere will not be regarded as a bar to presentation, provided that the work represents recent research

The Committee extends an invitation to all research workers of Greater New York City and of neighboring cities within a radius of one hundred miles to submit an abstract, not to exceed two hundred words in length, of proposed presentation to the Secretary of the Committee on Medical Education of the Academy not later than March 1,

On receipt, a formal invitation will be extended by the Committee to the authors of papers selected for presentation to participate in this program.

### IF WE CAN KEEP OUR HEADS

There is no justification for the often careless or smug assertion that a postwar economic collapse is inevitable.

Let us look at the facts.

It is estimated that since 1940 we have as a nation piled up an extra one hundred billion dollars in purchasing power by the public. This will increase through 1944 by another twenty to thirty-five billions if we do not enter into excessive inflation. There is an additional three to eight billion dollars to be considered in our postwar planning if we consider the possibility of dismissal compensation and unemployment insurance to veterans and discharged war workers.

On the converse side, there is no question as to the pent-up demands accruing for various goods and commodities ranging from automobiles to housing

and household equipment.

There are, to sum up, both multitudinous needs

and the cash reserve to pay for them.

It is perfectly true that there are going to be some very sharp and painful cuts in postwar employment through certain industries; as, for example, in aircraft manufacturing, shipbuilding, ordnance, and railroading. The total drop may reach to six or seven million persons.

There are potential postwar employment gains, however, to offset these apparently staggering figures. The paper, textile, lumber, construction, and agricultural sectors, plus the trades, services, and nonpostponable public works, may require over ten million workers for full postwar uses.

It is further estimated that from one to three million people will return to schools and col-

leges.

There will probably be a postwar standing army

of from two to three millions.

A Department of Commerce economist with all and more of the above factors in mind estimates that the elimination of work hours in excess of forty per week, plus the retirement of older men and employed housewives, will then offset the return of soldiers to industry.

If all of these above summaries are even approximately correct, then our postwar period becomes a matter of planning rather than of emo-

tionalism.

Instead of being subjects of propagandism, we might rather straighten up and strive toward a certain few fundamentals. First, to prevent excessive inflation; second, to maintain our confidence in the continuation of free enterprise; third, to encourage new products and enlarged enterprise through a judicious tax program; and last, to prevent monopoly by either industrial cartels or labor unions, which might in the long run tend to throttle the development of lower prices and work for everyone who wishes it.

Is all this not a different approach than to fold up and to wait or plan for a government job? We, as doctors, have our places in the public economy and cannot shove our heads in the sands of indifference.—Editorial by Stanley W. Insley in Detroit Medical News

tensive experimental work. The value of protein diet as a protective measure against arsphenamine liver injury was first observed by Schifrin,26 and confirmed by Messenger and Hawkins,27 in Whipple's Laboratory at Rochester, New York. The effect of carbohydrates in protecting the liver cells has long been known. Choline deficiency causes extensive infiltration with fat; some amino acids (methionine, cystine) exert an effect on this process. Ravdin's work with amino acids has been mentioned before. Rich<sup>28</sup> demonstrated experimentally that an increase in vitamin B complex exerts an inhibitory effect on the development of cirrhosis in rabbits.

These remarks serve to indicate that in the treatment of hepatocellular disease the diet should be strictly confined to carbohydrates and easily digestible proteins; when the proteins cannot as yet be tolerated, intravenous administration of amino acids in order to keep up the nitrogen balance and prevent fatty changes in the liver should be resorted to. A vitamin B complex that is palatable and does not cause yeast-like regurgitation will aid in improving the appetite.

Often, throughout the entire course of jaundice, dilute hydrochloric acid, 10 drops in 8 ounces of water, should be sipped through a glass tube with meals. Small frequent meals, about five daily, are desirable. Carbohydrates should consist mainly of white bread, cereals, potatoes, custards; proteins of vegetables such as peas and lima beans, pot cheese, fish and chicken, and egg albumen. Fats should be withheld even during the time of convalescence, until the color of the stool has returned to normal and the bilirubin in the blood gives normal values. Small quantities should be allowed gradually, beginning with a teaspoonful of butter in 24 hours, or 2 ounces of sweet cream, or olive oil mixed with lemon juice poured over lettuce.

There is no specific medication to alleviate jaundice. Symptomatic treatment, in addition to dilute HCl, may consist in trying to overcome constipation, which is usually very marked at the height of jaundice. H. Eppinger advises as much as 0.5 Gm. three times daily, which we believe to be excessive and liable to cause gingivitis and stomatitis. Small doses, 0.03 Gm. of calomel every three or four days, to be followed by citrate of magnesia, are very beneficial. Although anemia is rare, it is present at times, in which case there is also macrocytosis. Daily intramuscular injections of liver and iron by mouth are effective. If jaundice persists for more than four or five weeks and has a tendency to deepen, and the bilirubin and icteric index in the blood increase, one may resort to

giving 10-20 units of insulin in daily injection preceded by 8 ounces of orange juice and h lowed by a carbohydrate meal.

### Conclusions

- 1. Hepatocellular catarrhal icterus and po vaccinal hepatitis are symptomatically alil Duration of the prodromal stage in catarrh icterus is six to nine days. It is considerab shorter than in postvaccinal hepatitis, in whi the gastrointestinal symptoms may prece jaundice by several weeks.
- The average course of hepatocellul catarrhal icterus is five or six weeks, with cor plete and rapid recovery. In postvaccin hepatitis, although the jaundice may not l pronounced, convalescence is extremely slov The patient may have disturbed appetite, sligh. secondary anemia, and elevation of bilirubin in the blood for several months.
- Postvaccinal hepatitis is most likely due to a virus contained in some of the stocks of vaccine for yellow fever.
- Postvaccinal hepatitis is pathologically a true hepatitis, but fortunately reversible in the majority of instances.
- 5. The simple Volhard water test, which is of great diagnostic and prognostic value, should be carried out more often.
- Proteins should constitute an important part of the dietetic regimen. When the patient cannot tolerate proteins because of digestive disturbance, amino acids should be given intrave-
- Intravenous glucose administration in the preicteric stage is an important prophylactic measure against possible dehydration. It serves the immediate purpose of lessening the severity of jaundice, and also shortens the course of the disease.
- In pro-Treatment is symptomatic. tracted jaundice, injections of 10 to 20 units of insulin daily are of great value.

in the average case of congestive heart failure or edema from other causes, but salt restriction is

The average, normal person takes about 10 Gm. of salt a day and retains none of it over a period of time, but the patient with heart failure with edema, and also with edema from other causes, has a diminished capacity to excrete salt. These patients tend to retain salt when taking 10 Gm. daily, and some individuals are so sensitive to salt intake that matters go badly until the salt intake is reduced to about a gram a day. It is very difficult to reduce the salt intake below a gram a day and still maintain normal and adequate protein intake. The restriction, therefore, has a range somewhere between the normal of about 10 Gm. down to about 1 Gm. a day.

Now we come to the acids. We said that the extracellular fluid or edema fluid is a solution, an alkaline solution chiefly of sodium salts. administration of acids provides a threat to the acid-base equilibrium which excites the kidney to excrete base and the excretion of base by the kidney puts in a call for base which is fixed in the extracellular or edema fluid, with the result that the edema disappears if acid radicals are added to the diets. This may be done in various ways. It may be done by adjusting the diet so as to provide one which gives an acid ash, a diet composed chiefly of meat and cereals, prunes, cranberries, but no vegetables. Another way in which this may be done is to administer ammonium chloride or hydrochloric acid.

Every patient with edema and heart failure should, of course, be digitalized. We shall not go into this matter further here.

Finally, the administration of the organic mercurials deserves much consideration. The organic mercurial diuretic acts upon the kidney chiefly to impair tubular reabsorption. It causes an increase in the urine flow. The diuresis is chiefly a salt diuresis. Not only the water increases in the urine but the sodium base increases and increases in concentration as well as in the total amount, which suggests that the water leaves the tissues as a consequence of the loss of salt from the extracellular tissues.

Abundant water intake, salt restriction, administration of acids, digitalis, and organic mercurials may all be necessary or desirable in a given case. In some cases one or another may accomplish the purpose; in others a combination of some of them may be required.

There is a system of treatment of edema which provides for practically nothing more than virtual flooding of the patient with water as a means of abolishing edema. That is perhaps not the best system in most cases. There are individuals in whom it is not necessary to restrict

the salt intake. Digitalization alone will accomplish all the results in some. There are some in whom digitalis together with mercurials will effect all of the desired results without the troublesome salt restriction. There are still others in whom, after all of this is done, there is no clearing of the edema unless salt is greatly restricted.

Now a few words more about the organic mercurials. There are two outstanding defects in the prevailing use of the organic mercurials. One is that they are reserved for special cases, cases which manifest themselves in a pitting edema of the legs, enlargement of the liver, rales of the lungs, or ascites. These are the usual type of edema. It is often difficult to secure the use of organic mercurials when patients fail to show one or another of these signs.

The second defect is that the system fails to provide adequately for maintenance of the effect of the diuretic.

We are much further ahead in digitalis therapy. Around the turn of the century digitalis was also badly used. The patient was digitalized, the failure subsided, and then he was allowed to carry on without drug until enough distress accumulated to warrant another course. This system has been abandoned for digitalis, but it is still in vogue for the mercurial diuretics. The patient receives the diuretic to clear the edema, and then is allowed to carry on without it until fluid again accumulates.

How often should the dose be repeated? How often may it be repeated? We secure part of our information from the speed of excretion of the organic mercurials. If the dose is excreted completely in less than twenty-four hours, it may be repeated every twenty-four hours. It is often not necessary to give a dose as frequently as that, but it may be so given. By the method of trial and error, one decides in any given case whether the dose should be given once a day, once every other day, once every third or fourth day, or once a week.

The best guide to the proper interval is the body weight of the patient. The daily weight is probably a better indication than the more troublesome fluid intake and output measurements. The interval should be such as to maintain the weight at the low resistant level to which the early doses reduced it. Other symptoms are also useful as guides.

With respect to the group of cases for which the mercurials are reserved, I said that most physicians hold off giving organic mercurials by reason of the fact that they wait for an enlarged liver, edema of the legs, or rales in the lungs. There is a very large group of patients with failure of the left side of the heart who have

# Therapeutics

# CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the March 1 issue and will concern "Basic Principles in the Use of Drugs for the Local Treatment of Diseases of the Skin."

# Treatment of Edema by Drugs

Dr. McKeen Cattell: During the hour we plan to continue the discussion of water balance which we began last time, with special reference to the drug treatment of edema. The discussion will be opened by Dr. Gold.

Dr. Harry Gold: Last time Dr. Barr presented an account of factors responsible for the maintenance of normal distribution of water in the body, more particularly the better-known factors, such as the gradient of hydrostatic pressure in the capillaries from the arterial to the venous side, the osmotic pressure of proteins, and the distribution of electrolytes on the two sides of the cell membrane. By way of illustration with the case of heart failure, he pointed out that several factors might participate at one time in upsetting the balance and leading to edema, or the reverse—abolishing edema.

From the discussion that followed I think it must have become pretty clear that one can ask many questions about the mechanism of edema which cannot be answered satisfactorily, and yet there are several well-known facts, chemical and physiologic, concerning the mechanism of edema which serve to provide a sound base for the measures which are used in its treatment.

I might add at this point that there are very few therapeutic fields in which the rewards are so high as in the treatment of edema if the correct measures are applied in the correct way.

I find it very helpful in my own thinking to start with the proposition that e ema is not simply an accumulation of water in the body, but the accumulation of a solution of salt. Edema fluid is an increased amount of extracellular fluid, and extracellular fluid is not only water but a solution of salts—about a 1 per cent solution of salt. Every 100 cc. contains nearly a gram of salts, composed chiefly of sodium chloride and to some extent of sodium bicarbonate. It is an alkaline solution with a pH of about 7.4.

This view of edema fluid is fundamental to the interpretation of the measures that are employed for reducing or abolishing edema.

The composition of this fluid is fairly constant

and we cannot increase it or diminish it except by breaking down the balance by which its composition is maintained.

In the treatment of any case of edema there are at least six factors which come to mind at once. There are others, perhaps, but these are the important ones: (1) water; (2) salt; (3) acids; (4) measures for the diminution of the hydrostatic pressure; (5) digitalis, if it happens to be a case of heart failure; and (6) organic mercurials.

The prevailing practice with respect to water in the treatment of edema is to restrict water intake. There must be relatively few patients who are treated for edema at the present time without restriction of water, and this in spite of the fact that the best evidence indicates that there is no primary trouble in the excretion of water in most patients with edema. The patient with heart failure or with nephritis seems to retain a high capacity to excrete water, and it does not seem to matter whether he takes in 800 cc. or 3,000 or 4,000 cc. of water. He excretes it all, provided certain other conditions are met. There is fairly satisfactory evidence that the administration of water, plain water, to a patient with edema may not only fail to increase the edema, but that if enough water is given, the edema may diminish. That may well be due to the fact that when a patient drinks water he passes urine, and the urine is a solution of salts, and the less salt remaining in the extracellular spaces the less water is held.

The best evidence indicates that water restriction in the patient with edema is not necessary, provided other essential factors receive appropriate attention.

What are the other factors? If one gives a normal individual a liter of water he excretes it all in the urine within four or five hours. If one gives the subject a liter of salt water, twenty-four to forty-eight hours will elapse before he excretes it all. So then the determining factor in the retention of water in the body is the salt. Water restriction, therefore, is not necessary

until the edema all goes. After these measures there is little that can be accomplished by adding ammonium chloride or the xanthines in the vast majority of cases. There are occasional cases in which ammonium chloride may be tried if the effect by the mercurial alone is incomplete.

Dr. Modell has showed that after the organic mercurials, ammonium chloride may make about a 15 per cent contribution to the diuretic effect. In the large majority of cases it is unnecessary. The system I suggest has the merit of simplification of therapy with the most effective agent used first, and usually alone.

Dr. EUGENE F. DuBois: May I ask, are there any serious disadvantages in making a patient lose the edema too fast by too much diuresis?

Dr. Gold: Yes, indeed! Excessive diuresis causes many symptoms. The patient may vomit. He develops intense weakness and prostration, with soreness and cramps of the muscles. He is often quite sick. These patients behave very much as those with socalled water intoxication, probably owing to the excessive loss of salt in proportion to the loss of water. I think it is a good plan to adjust dosage so as to avoid securing more than about 2 extra liters of urine per day in an edematous patient. Perhaps we could put it better this way: Avoid the loss of more than about 3 to 4 pounds per day. With the loss of more than that the incidence of disagreeable symptoms rises sharply.

Dr. David P. Barr: In listing the dangers of rapid diuresis, should it also be mentioned that the sudden loss of edema fluid in cases of nitrogen retention may lead to uremia?

Dr. Gold: Yes, indeed, I think that is an important point.

Dr. Ephram Shorn: That calls attention to a numerically small group, but one that is difficult to deal with therapeutically. I refer to patients with edema associated with Bright's disease. In these, oliguria occurs in association with low carbon dioxide combining power. It is often necessary to raise the carbon dioxide combining power by giving sodium lactate or sodium bicarbonate before diuresis is possible. An excellent diuresis can be achieved by just that one measure alone. Conversely, those patients should under no circumstances receive acids.

Dr. DuBois: I remember also that some of our patients complained bitterly that they could not get any sleep at night. They were too busy passing urine.

Dr. Gold: I think that is a practical and important matter. One ought to give the or-

ganic mercurials in the morning and not at night. The patient then gets through with most of the business before bedtime.

Dr. CATTELL: Perhaps we might now hear from Dr. Modell.

Dr. Walter Modell: In evaluating the difficulties which have arisen following the administration of the mercurial diuretics, the large number of patients and the type of patients receiving these drugs should be considered. Not only is the use of these drugs very extensive, but many of the patients who receive them get them repeatedly, and by now there is a rather large group which have received well over 500 injections. In addition, as Dr. Gold has pointed out, it is the practice of many physicians to give mercurials only to those patients who are urgently ill; the type of patient in whom sudden death is not an uncommon occurrence.

The toxic symptoms which follow the use of mercurials may be divided into three categories. I give them in the order of increasing importance. First, the symptoms of mercurialism; second, the immediate symptoms due to idiosyncrasy; and third, the delayed symptoms due to salt loss.

The symptoms of mercurialism include stomatitis, colitis, renal damage—findings which are usually associated with the administration of ionic mercury. In the diuretics, mercury is in a nonionized organic form, is rapidly excreted, a large part of it within six hours, and practically all of it within twenty-four hours.

The recorded number of authenticated cases of mercurialism following the use of the organic mercurial diuretics is very small indeed. But because of the possible danger of renal damage a special note of warning is usually sounded concerning their use in patients with renal disease. However, it is a practice with many clinicians merely to use these drugs with greater caution in patients with renal disease. It is difficult to avoid their use entirely in patients with renal damage, since renal damage is a common finding in many chronic cardiacs, especially those with arteriosclerosis.

Immediate symptoms following the mercurials which may be ascribed to idiosyncrasy or hypersensitivity include dizziness, weakness, substernal oppression, dyspnea, collapse, change in cardiac rhythm, and death.

Until relatively recently it was said that there had been no death immediately following the intravenous administration of mercupurin to cardiacs. The fact that a handful of such deaths have since been reported serves to emphasize that these occurrences are relatively rare, and also to indicate that such things may occur.

neither edema of the legs, enlargement of the liver, nor rales, but they have edema of the lungs which may give no rales. These patients are short of breath. They may be subject to paroxysms of nocturnal dyspnea. They may be able to do a day's work but from time to time develop an attack of pulmonary edema. They have an elevated circulation time of the lungs, an elevated venous pressure in the pulmonary circulation. They are patients with failure of the left side of the heart. This group of individuals obtains very little help from digitalis. In this group, the organic mercurials, if used by a system involving first the production of the full effects and then the maintenance of these effects by appropriate doses at appropriate intervals, produce results which in every way equal the striking and dramatic results of digitalis in the classical case of early heart failure with auricular fibrillation.

The point I want to emphasize again is this: There is a large field for the use of the organic mercurials in the treatment of a group of patients commonly overlooked, in whom there is failure with congestion but who do not show the classical signs which we ordinarily associate with congestion: edema, rales, liver enlargement, and swelling of the legs.

DR. CATTELL: I want to call on Dr. Modell in a moment, but perhaps we might first see whether there is any disagreement with what Dr. Gold has told us.

Dr. C. H. Wheeler: I should like to challenge Dr. Gold on the omission of two things from his list, and the first of those would be protein, because it is my impression that there is a group of patients who have edema in association with or because of hypoproteinemia, in whom all other measures may be completely ineffective until proteins are restored to normal. In other words, there are patients in whom repeated plasma infusion may produce a much more dramatic diuresis than any of the measures which Dr. Gold has emphasized.

Second, I wonder why you have omitted the caffeine-theophylline-theobromine group of diuretics from your list, because it is my impression that they may be very useful. I am sure we have many patients on the ward who have been digitalized and brought to a basal level, so to speak, who continue to show diuresis when given theocalcin in daily doses.

DR. Gold: The first measure—the use of protein—I omitted by reason of the fact that I was listing only the measures which apply to the vast majority of cases. There is no doubt of the importance of protein. However, one does not very often encounter a patient with edema n whom the administration of protein is a solu-

tion to the problem. There are, of course, some such cases. There are other relatively rare ones; for example, the wet beriberi, treated with thiamine.

The other omission, the xanthines, is made purely with malice aforethought. I wanted to emphasize the surpassing importance of the organic mercurials as diuretics by mentioning only them, and to emphasize the relative lack of importance of the other diuretics by omitting all mention of them. The mercurial diuretics give us trouble. They have to be injected usually. If some of the solution spills into the perivenous tissues a painful nodule forms and phlebitis may result. For these and other reasons we tend to drift toward other oral diuretics. It is mighty uncommon in my experience, however, that one is able to carry a patient along satisfactorily by means of any one of the xanthines orally. I refer now to patients who have recurring edema and in whom we have proved continued dependence on a diuretic action.

When I give the xanthines in such doses as patients can tolerate they rarely show more than a slight effect on the edema. As soon as the doses are raised sufficiently to give effective diuresis, after four or five days, they develop so much trouble in the form of vomiting, cramps, diarrhea, and nervousness as to make it impossible to continue. This applies to the whole group of the xanthines. As for the acid-forming diuretics, they also are not very effective. They produce some loss of edema, but as soon as the doses are increased to 8 or 10 Gm. a day, where their efficiency is fairly high, they begin to behave like saline laxatives.

DR. WHEELER: It is not my thought that the xanthines and ammonium chloride should ever be used instead of the mercurials, but that they may often be used in addition to the mercurials. In other words, a patient may get rid of his edema faster if he is subjected to salt deprivation, the administration of ammonium chloride, the daily administration of theocalcin, and the administration, say, of mercupurin every third or fourth day. On such a regimen he will lose edema somewhat faster than with the mercurial alone. Would you take issue with that?

DR. Gold: I would take issue with that as a routine. In a patient with heart failure, my own way is as follows: let him have all the water he wants to drink. Tell him to put no salt in his food. That is one way of securing moderate salt restriction since there is still some salt in his food although he adds none. Digitalize him fully. If all the edema does not disappear, then begin the use of the organic mercurial. Adjust the dosage and frequency of repetition

four hours suffice for the elimination of an average dose of 1 cc. of mercupurin?

Dr. Modell: There are some data indicating that twenty-four hours suffice in normal men and animals, but I am not sure of the proof for the statement that in the presence of oliguria a longer time may be required.

DR. Gold: I don't believe there is any satisfactory indication that cumulation of the mercurial occurs with a daily dose of mercupurin if a reasonable urine output is maintained, such as 1,000 cc. a day.

DR. Modell: Dr. Gold, if a patient with edema who has a fair urine output shows no increase of urine after the mercurial, would you be concerned about the possibility of retarded elimination of mercupurin?

Dr. Gold: I think it does not take much urine to excrete a dose of organic mercurial. If the patient is not passing any urine that is another matter. If there is anywhere near a normal urine excretion, even though no diuresis results from use of the drug, there is virtually no danger of accumulation of the organic mercurials with the usual plans of administration. There is much too much fear about the possibility of such danger, as the result of which the drug is withheld when patients are badly in need of it.

Dr. Robert F. Pitts: Your emphasis, Dr. Gold, seems to be a primary attack on salt excretion. Do you think that an attack on water excretion carried out simultaneously might possibly reduce some of the disagreeable symptoms which are described for excessive salt loss? In other words, combine some osmotic variety of diuretic substance to pull out water at the same time that you get the water out indirectly by salt loss?

Dr. Gold: You mean that one should avoid the disproportion between salt and water which gives rise to the disagreeable symptoms? That sounds like a good idea, and it might conceivably be done by simultaneous use of urea or glucose.

Dr. Wheeler: Dr. Gold, I should like to nag you a little more about these other substances. I want again to refer to the point that there are patients who for one reason or another find it difficult to see the doctor every day or every second or third day for a mercurial injection, and I wonder if you would not admit that the xanthines might be useful in those cases. Then I want also to ask you about urea. Some of us around the hospital have felt that in the past urea has often served as a useful diuretic. The chief objection to urea on the part of the patient is the awful taste.

Dr. Gold: Dr. Wheeler, I could not very

well grant your point about the xanthines without spoiling my thesis. I would say this: if the
daily injection becomes a difficult problem, one
can do better than use the xanthines. Try
out the rectal suppository of salyrgan with
theophylline or the mercurin suppository. There
are more individuals whose rectum will tolerate
these for some time than there are whose stomachs will tolerate effective doses of the xanthines.
I shared the view which you hold about the
xanthines once upon a time. I have abandoned it.

Dr. Modell: Dr. Gold, do you think we might mention the salyrgan with theophylline tablet which is now on the market? In my experience one case in twenty tolerates an effective daily dose. If the dose is large enough it is diuretic.

Dr. CATTELL: Dr. Shorr, I think you had a question.

Dr. Shorn: Is there any validity in the use of potassium chloride as a salting agent for patients who are on sodium restriction?

Dr. Gold: Yes, potassium chloride, while not possessing quite the savor of sodium chloride, is nevertheless welcome to the patient on salt restriction. It makes the food more palatable.

Potassium chloride is itself a diuretic and there are some studies showing that very effective diuresis can be produced by 5 or 10 Gm. of potassium chloride given daily to certain patients with edema, particularly in nephritis with edema. The mechanism of potassium chloride diuresis is not entirely clear. When one gives potassium salts, one factor may well be that the kidney, being partially blind to the difference between potassium and sodium, excretes base, and in that way takes out a large amount of sodium. The loss of sodium, of course, leads to the mobilization of water from the extracellular spaces.

Dr. Shorr: It is my impression that in Bright's disease with insufficiency the potassium content of the blood is likely to be lowered.

Dr. DvBors: I should like to ask Dr. Gold about the diuretic effect of rest in bed.

Dr. Gold: The diuretic effect of rest in bed is very considerable. There are many patients with heart failure and edema who as a result of rest in bed alone develop active diuresis, and the edema disappears. Complete disappearance of the edema from rest in bed alone is not the rule, but a high degree of improvement is. The more advanced the failure, the less complete is the improvement from rest in bed alone. The response to rest in bed provides information of prognostic importance.

Dr. CATTELL: It would be interesting to have a brief statement from Dr. Modell regard-

It is important to note that sensitivity to the mercurials may apparently develop after many injections and without previous warning. One patient who died received some forty injections of mercurial diuretics without symptoms prior to the last one. However, in three of four cases there was a warning. In one there was transient heart block; in another, substernal oppression; in another, the patient complained of a "very peculiar feeling" after his injections.

We have under observation now a man who about a year ago, after receiving some twenty or thirty weekly injections of mercupurin, suffered marked dizziness and weakness after 2 cc. administered intravenously. mercupurin Spontaneous recovery occurred in an hour. The following week the patient was given half the dose, 1 cc. A similar episode of less severity followed. Since that time he has received over fifty weekly injections of salyrgan-theophylline without reaction. In instances in which symptoms of idiosyncrasy or sensitivity have appeared it may be possible, therefore, to avoid repetition by the use of another mercurial diuretic.

The most frequent symptoms are those which appear the day after the injection. They are due to the diuresis which is produced by the mercurials and are most pronounced after massive diuresis. The large amount of urine, as Dr. Gold explained, which flows out of the body as a result of the mercurials washes away with it a considerable amount of chlorides and other electrolytes. Such patients usually suffer from electrolyte imbalance and symptoms similar to heat cramps may develop. These symptoms may be prevented and relieved by the use of ammonium chloride.

Redigitalization also has been advanced as a possible source of difficulty after massive diuresis. It has been explained that the mobilization of edema fluid may liberate at the same time digitalis bodies which have been stored in it. Although attention has been directed to this phenomenon for many years, proven cases are difficult to find in the literature. I mention it here merely for the sake of completeness.

DR. CATTELL: Are there further questions or discussion?

INTERN: The statement is sometimes made that following an injection of mercupurin there is a very rapid hemodilution with increase in circulating blood volume. I wonder what data we might have on that subject, because this has often given pause in treating a patient with coronary occlusion.

Dr. Gold: That question has been debated and I would say that the opposing reports on

the subject are about equally balanced at the present time.

The story started with the notion that the organic mercurials exerted an extrarenal action. What they did first was to liberate water and dilute the blood. This motivated the diuretic cycle. After a few years workers began to fail to find hemodilution. It seems probable that if there is a hemodilution it is very small, and should prove no bar to the use of the mercurial in coronary occlusion.

DR. DuBois: Not so very long ago, when I was an intern, there were various methods of treating edema in one of the best hospitals in this city, and if I remember rightly they occasionally put plasters of belladonna or plasters containing digitalis over the kidneys. They exposed the patients to hot air in bed tents and used wet packs. Then there was the method of extreme catharsis.

It might be interesting to review the manner in which these therapeutic measures were finally disposed of. I think some of them are still used.

DR. Gold: I should not be surprised if all of these measures promoted sweating of either the whole man or a part of him. That might increase the salt loss and anything which increases the salt loss tends to decrease edema. They must have been quite ineffectual, however, by comparison with the heavy artillery which we now employ.

Beyond doubt, the saline cathartics have value. The saline cathartics act chiefly by holding fluid in the intestine. The patient takes a small dose of a saline cathartic and then passes the equivalent of a quart enema. He loses water and probably salt as well. But again, I think that by comparison with what we use today, these measures must have proved very feeble. Dr. DuBois, you would know better than I how effectual they

Dr. DuBors: As interns we were impressed chiefly by the fact that the edema did not disappear, but also that the patient was made extremely uncomfortable. When a patient with heart disease and nephritis was put in a hot pack and left there for several hours he was most uncomfortable, as a normal man would be.

Those who were subjected to vigorous catharsis had to spend a considerable amount of energy on the bed pan.

I think it was Dr. Henry Christian, was it not, who pointed out the advantages to the neighbors if the kidneys were used instead of the bowels? He has some classical quotations on that.

Dr. Shorn: Is the elimination of mercurials impaired in renal insufficiency? Does twenty-

special problems which may require particular measures, such as rest in bed as a means of reducing hydrostatic pressure, thiamine in the edema of beriberi, and high protein intake for the edema of nutritional origin.

Edema fluid is not only water but a solution of salts of which sodium chloride is the most abundant. Patients excrete water very quickly, but if the water is given with salt it is retained for a long time and deposited in the tissues in the form of edema. Water restriction is widely practiced. It seems to be unnecessary. What is necessary is salt restriction. If that is done, the patient may take as much water as he desires. Some cases of edema require only one of the measures listed above; other cases require all of them.

Saline cathartics and vigorous sweating have been used in the past for the purpose of reducing edema but they are not sufficiently effective to play any part in the modern treatment. The xanthines, such as theocalcin and theophylline, received some defense as useful diuretic agents, but the view was also expressed that it is so rare to find patients who can take large enough doses without gastrointestinal symptoms that it is better to apply the mercurial diuretics from the beginning rather than the oral diuretics which, in the experience of some, do not give sufficiently consistent results to warrant their trial in the average case. The details of the use of mercupurin or salyrgan with theophylline were discussed. Smaller doses (1 cc.) at more frequent intervals are more effective than larger doses (2 cc.) at less frequent intervals. They may be given daily without danger. There have been some deaths from the mercurials, but on the whole their danger is small when one considers their extensive use. Excessive diuresis is to be avoided because it is likely to produce nausea, vomiting, prostration and muscular cramps. These may be controlled by the use of smaller doses of the organic mercurials. Ammonium chloride in doses of about 4 to 8 Gm. daily enhances the effectiveness of the mercurial diuretics by an average of about 15 per cent, but most cases do sufficiently well without it. The mechanism of the action of the organic mercurials was discussed. There seems to be no contraindication to their use, and the danger of poisoning, even in renal disease, is negligible if a fair urine output is present. The weight of the patient is a useful guide in the treatment with the organic mercurials and one of the plans suggested was to give the mercurial at frequent intervals, even daily, until the weight declines to a resistant level at which it may be maintained by doses at longer intervals. In cases in which injections are not feasible, an attempt should be made to control the condition with the rectal suppository or the oral tablet of the diuretic.

The mercurial diuretics are frequently reserved for patients with frank signs of edema such as rales, swelling of the legs, or ascites. Attention was called to the large field of usefulness of these diuretics in failure of the left side of the heart, in which none of these signs may be present, but in which the patient is subject to attacks of pulmonary edema and paroxysms of dyspnea. In these the appropriate use of the organic mercurials produces therapeutic results which are unobtainable with any other measures.

## IT IS NO DISGRACE TO BE SOMEWHAT NEUROTIC

"It is good to be somewhat neurotic," declares Dr. Walter C. Alvarez, of the Mayo Clinic, in his new book, Nervousness, Indigestion and Pain (Hoeber).

÷

This should cheer up many a person who, besides his or her other sufferings, has to bear the feeling of blame or disgrace that is too often associated with the word "neurotic." Actually, the term can be taken as a compliment, Dr. Alvarez tells his patients.

"If a woman is to have any vivacity and social charm she must be nervous and highly sensitive," he declares. "Without these qualities she cannot be wide-awake and responsive and interested in people and in everything that is going on about her; without it her face will not be mobile and attractive, her eyes will not light up, and her conversation will not be animated. But it is just this ability to feel keenly and to react strongly that commonly brings in its train fatigue and suffering."

The nervous makeup that can make a person feel "in the seventh heaven" while hearing a symphony, or weep at a sad play, also can make a person feel great distress or even pain after a hearty meal which would give a less nervous person a comfortable feeling of having his stomach well filled.

Although Dr. Alvarez has written this book for physicians, especially those just starting to practice medicine, there is much in it that will help the intelligent person whose nerves often make him sick and weary. One of the important points which neurotic patients may learn from the book is to recognize what they are really like.

Dr. Alvarez has pointed out that half the battle for relief from suffering and undue fatigue may be won if the patient can stop worrying because his sensitive nerves make him feel unpleasant things and minor annoyances just as keenly as he feels the beauty of music or delight and joy in pleasant sen-

sations .- Science News Letter

ing the optimal doses of mercurial diuretics, a problem which he has investigated.

Dr. Modell: We compared different doses in the same patient. We found that while a large dose gave a larger total diuresis, a small dose gave more diuresis per cc. of the drug than a larger dose. Also, two small doses gave more diuresis than one large dose. Patients were much happier when given 1 cc. of mercupurin, say on Wednesday and Saturday, than 2 cc. one day a week. They did not accumulate so much edema in the case of the two smaller They did not suffer as much from dyspnea and sleeplessness. Nor did they suffer as much from cramps and other effects seen in the case of massive diuresis. All the results point to the advantage of smaller doses repeated at short intervals over larger doses once a week. It is important to try to maintain a daily water balance instead of a weekly one.

Dr. Cattell: Are there further questions? Dr. Walsh McDermott: I should like to add that the emphasis which has been put on the use of the organic mercurials in the absence of dropsy is in line with what we have been teaching. Medical students don't seem to grasp it for some reason. I am glad to see the idea re-emphasized at this conference.

There is one group of patients who have paroxysmal nocturnal dyspnea who cannot be treated daily. Incredible as it may seem, many of them are working, and an oral diuretic which would reinforce the action of the intravenous mercupurin is essential in that group of patients, but not in the dropsical ones.

Dr. Gold: I should certainly agree to that. An oral diuretic which would reinforce the parenteral one would certanly be valuable.

DR. SHORR: Do you use ammonium chloride?
DR. GOLD: Yes, we use ammonium chloride.
It adds something to the efficacy of the organic mercurial. Its contribution to the diuretic result is, however, relatively small. It does not fully meet the need for an oral diuretic.

As for the xanthines, we have given them in a routine fashion to patients with edema, but on examination of our experiences, we have come to doubt whether they are worth the trouble.

Dr. McDermott: We have used them very little.

DR. GOLD: I am in full accord with the view that an oral effective diuretic is desirable. My point is, however, that little dependence can be placed on those that we have.

DR. WHEELER: We have had just the opposite experience, Dr. Gold, because we have had patients who have been in the hospital for a month or six weeks and were thoroughly digitalized. After they seemed to have reached a state

where nothing further could be expected from bed rest and other measures, they were given theocalcin, a gram four times a day. This would carry them along over a period of several weeks without the toxic effects you describe, and would produce an increase of urine volume, from 600 to 700 cc. to 1,000 and sometimes even 1,500 cc. a day, so that we were convinced that some of these substances were useful.

Dr. Gold: The xanthines are diuretic agents. There is no doubt of that. Some years ago Dr. Goldring published a study from Bellevue Hospital in which he showed in well-controlled experiments that large doses of xanthines daily produce good diuresis in bed patients with heart failure.

The large doses which are necessary for such effects cannot be continued for any length of time. The ambulant patient who is seriously ill and likely to go downhill rapidly if active diuresis is not maintained cannot in our experience be carried along satisfactorily with the xanthines.

We have a fairly large group of such patients in our clinics and matters went very badly until a system was worked out by which they were able to secure injections of the organic mercurials. The xanthines do such a questionable job that in an account of effective diuretics I believe that it is justifiable to emphasize their relative ineffectiveness by omitting them from consideration. In such cases as the type you cited, Dr. Wheeler, I wonder whether you could be certain that they would not get on equally well without the theocalcin. I might add that I have little doubt that an occasional patient might be encountered who is very sensitive to the diuretic action of the xanthines and may be benefited by them. My own experience indicates that these cases must be rare.

The prevailing practice seems to be to try one of the xanthines or other oral diuretic first and to struggle along with them for a long time. In the case of patients who are badly in need of active diuresis we practically always in the end fall back on the drugs which really help, namely, the organic mercurials. That being the case, I should like to urge their use in the beginning.

## Summary

Dr. Gold: We may now summarize briefly the chief points of this discussion on the drug therapy of edema.

Great progress has been made in this field of treatment. Physiologic objectives have been more clearly defined. There are at least five important measures which require consideration in every case of edema: water, salt, acids, digitalis, and diuretics. There are, in addition,

League of Red Cross Societies, the International Committee for Intellectual Cooperation, and the

European Rotary.

The I.U.S. will carry out a work of true and active fraternity, a work of peace. It is a symbol of the new age which the whole world awaits and desires. It is a realization of those values which men need now more than ever, and of the spirit in which Switzerland wishes to live in the midst of

The I.U.S. is under the patronage of the Swiss Government, which made a grant of half a million Swiss francs toward the foundation of the Sanatorium and itself introduced the project to all other governments for their collaboration.

The creation of the I.U.S. is being made possible by the subscription of "founder's shares" at 25,000 Swiss francs each. These entitle their subscribers to permanent ownership of one of the beds and to membership in the governing body. Governments, universities and colleges, student organizations, towns and cities, industrial concerns, philanthropic institutions, and private individuals are invited to communicate the number of shares they wish to reserve for themselves. The smallest gifts are accepted with very sincere gratitude.

The governments of Belgium and Luxembourg have already joined Switzerland in the work of bringing the International University Sanatorium into existence. The first six non-Swiss beds were subscribed for in these two countries.

The building of the sanatorium will begin as soon as a hundred beds have been bought. Up to the present forty beds have been taken, two of them by Egypt in time of war.

### A.M.A. SAYS USE OF MINERAL OIL IN FOOD MAY BE HARMFUL

On the basis of medical reports showing the harmful effects that may result from the ingestion of mineral oil (liquid petrolatum), "there can be no justification for the incorporation of liquid petrolatum in foods," the Council on Foods and Nutrition of the American Medical Association declares in a report in the December 11, 1943, issue of the Journal

of the Association.
"It has been shown," the report continues, "that the ingestion of liquid petrolatum is capable of interfering seriously with the absorption of carotene, and vitamin K. vitamin D, calcium and phosphorus, and vitamin K. The effects of its prolonged use have not been thoroughly investigated, but there is sufficient evidence of possible harmful effects to justify the con-clusion that its indiscriminate use in foods or in cooking is not in the interests of good nutrition and any such use should be under careful supervision of

a physician.
"The Council previously has accepted, with a special requirement that the products be promoted for use only under the direction of a physician, salad dressing or imitation mayonnaise containing mineral oil, for use in therapeutic diets. In view of the abuses which have developed through the production and sale of food products containing mineral oil to the public, the impracticability of providing suitable and adequate warning of the possible harmfulness of such preparations, and the fact that physicians wishing patients to use such products readily can supply directions for their preparation on a small scale from liquid patrollature and other on a small scale from liquid petrolatum and other ingredients, the Council has voted, on the basis of evidence reviewed in the present report, to withdraw its acceptance of these products."

The Council points out that there are conflicting the Council points out that there are communing views regarding the effect of mineral oil per se on the alimentary tract. Many physicians consider mineral oil preparations the laxative of choice. "It is probable," the Council says, "that under medical supervision mineral oil can be properly used, but the ease of obtaining the preparations as well. but the ease of obtaining the preparations as well as other laxative drugs readily leads to abuse. Proctologists have experienced difficulty in visualizing the second of ing the wall of the rectum because of an adhering film of oil in persons who take liquid petrolatum. The seepage of mineral oil is well known to be one of the discomforts that may attend the use of this

substance. "J. W. Morgan has written forcefully about the need of caution in the use of liquid petrolatum. He has mentioned a syndrome to which he has ascribed the term 'mineral oil poisoning' which may result from the continual oral administration of liquid petrolatum and which is relieved by discontinuance of the oil together with supportive measures to overcome the weakness which accompanies this syndrome. The most frequent signs and symptoms are anorexia, indigestion, flatulence, fatigue, nervousness, dyschesia, and anal leakage, accom-

panied in many cases by considerable loss of weight."

Commenting on the Council's report, the Journal

says:
"Basically, salad dressings made with mineral oil cannot be differentiated, except in a laboratory, from ordinary products containing true fats or oils like olive oil. Such products are frequently bought in large amounts by hotels and restaurants. The person who receives a salad on which such a dressing has been placed has no idea as to the nature of the material that is being used. Mineral oil is plentiful: it can be purchased without ration points and can be sold much more cheaply than can olive oil or other vegetable oils. . . . . Sometimes such products are vegetable oils.... Sometimes such products are sold in one to five gallon containers purchased largely by hotels and restaurants, since householders do not use such quantities. There are, for instance, a product called Thallon-Naise made in New York, a mayonnaise packed for H. L. Barker, Inc., New York, a mineral oil dressing made by J. H. Filbert, Inc., Baltimore, a product called Slenderit manufactured by Marquis Products Company of Portland, Orc., and Beck's Pure U. S. P. Mineral Oil furnished by Beck's Mayonnaise Products of Davenport, Iowa, as well as others. Mineral oil is used in the baking industry in the place of animal and vege-

## THE SWISS UNIVERSITY SANATORIUM AT LEYSIN, AND THE PROJECT OF THE INTERNATIONAL UNIVERSITY SANATORIUM AT LEYSIN\*

THE Swiss University Sanatorium aims at cur-L ing professors, tutors, lecturers, and male and female university students who are attacked by tuberculosis in a curable form or who have a predisposition to this disease. Professors and students of foreign universities are cordially welcomed when there is room available.

This institution was founded by the Swiss universities and the Federal School of Technology, and owes its existence to the years of effort and original initiative of its director, Dr. Louis C. Vauthier. It is situated at Leysin in the Vaudois Alps, one of the best of the Swiss climatic resorts (4,500 and 5,000 feet above sea level), and commands a magnificent panoramic view. It is provided with all modern scientific equipment and has forty single bedrooms. It was opened on October 1, 1922.

The University Sanatorium is a work of corporative solidarity. Professors and students of the Swiss universities have made an annual contribution of 20 and 10 francs, respectively, since its foundation, and this permits of a reduction in the daily fee for patients.

By grouping together students whose occupations and preoccupations are of a similar character, the University Sanatorium provides an environment with a very considerable influence for the good, both intellectually and morally.

The influence of intellectual work on the progress of patients who must undergo a cure of such long duration manifests itself very clearly, and its action is felt in all departments of their lives. In no case has quiet and regular work at fixed hours been found harmful. On the contrary, it has always been a powerful agent for good, at the same time a sedative and a tonic. It has given them a healthier and more balanced outlook, and preserved them from demoralization and neurasthenia. An optimism which takes possession of the whole being and acts upon its multiple functions has proved to be the essential result of the curative force emanating from mental activity.

The University Sanatorium furnishes its patients, as far as possible, with the means of continuing their work and their studies: chosen from their own teachers, who remain in

\* A release from the Official Information Bureau of Switzerland, 475 Fifth Avenue, New York City, F. Dossenbach, Director.

contact with them by letter and who come to see them; a library of 14,000 volumes; more than 150 journals and reviews in several languages; visits from and regular conferences with professors of all faculties, with writers and others. Together with intellectual work, music plays a very important part in the life of the Sanatorium. Famous artists constantly come of their own free will to delight the patients with a display of their art. Nor are moments of relaxation and entertainment lacking. The very character of the home is one of gaiety.

The establishment has its own lantern slides and films. A radio with headphone equipment is installed at every bedside and microphones allow the patients to hear concerts and conferences given in other parts of the house. It is also provided with a very well-equipped darkroom, a herbarium, collections of microscopic preparations and products of Helvetic pharmacopeia, and with mechanics' and carpenters' workshops.

Since the foundation of the University Sanatorium, 650 professors and students from 42 different countries have come to regain their health here. More than 1,000 scholars, writers, and artists, Swiss and foreign, have helped to enrich the Sanatorium's activities with knowledge and aid. One hundred and fifteen theses have been written, 425 examinations prepared and, very often, brilliantly passed during or immediately after the cure. A large number of patients have learned foreign languages during their stay, and all have profited by the general culture which permeates these surroundings and this life.

The Swiss University Sanatorium is the prototype and a partial realization of the International University Sanatorium at Leysin which Dr. Louis C. Vauthier, the initiator of the project, and an organizing committee (President, Professor A. Rohn, Chairman of the Governors of the Federal School of Technology in Zurich) are now bringing to completion in spite of the war. It is proposed to establish a sanatorium of 208 beds, which will also provide numerous university and social conveniences.

The International University Sanatorium is a work of pure idealism, and no personal, financial, national, or denominational interests whatever are involved. The project has the support of the great international student organizations, the International Union against Tuberculosis, the

288

may feel unloved or unwanted, and react with delinquent behavior. Children may feel discriminated against; they may feel jealous of their brothers and sisters. Parents often unwisely had a "favorite" child and compared the good traits of this model child with the bad faults of the other children in the home. Children may feel ridiculed by their parents or other relatives because of their difficulties in school or because of physical handicaps, and may resort to delinquent conduct. On the other hand, parents may fail to understand and appreciate their responsibilities to children and may allow them to be completely undisciplined in the school, home, and community. Poverty, poor housing, and unsanitary living conditions also contribute to delinquency. One of the chief sources of delinquency is the lack of supervised wholesome recreational outlets for children and adoles-

It has been shown repeatedly that there are certain parts of big cities from which the majority of delinquents come. In these areas there are few or no playgrounds or parks, and children must spend their leisure time in streets and alleys and they often associate with playmates with criminal family backgrounds.

Even in peacetime the community facilities available for children were inadequate in many sections of the country. Now, because of the war, these resources are more limited. There is insufficient personnel for many of the playgrounds and recreational centers. Schools are understaffed. The Children's Bureau in Washington reports that in the boom towns schools are unable to handle the increased enrollment, and in many states teachers are not available for many classrooms. In certain communities, due to budgetary consideration, there has been a decrease or cessation of recreational facilities and other socially preventative measures available for children,

Because of the war situation, many homes have already been disrupted, with one or both parents in the armed forces or in defense plants away from home, so that normal parental supervision is lacking, and the children, left unsupervised, fall in with older delinquents and soon develop antisocial conduct. Moreover, young girls, through feelings of patriotism, will engage in sex acts with members of the armed

forces, sometimes for pay, but frequently as a patriotic gesture.

Now, what can we do to check this recent increase in delinquency, and what can be done to prevent delinquency in general? All of us can help. Those women who have growing children should remain home with them and care for them. Moreover, the parents should provide healthy recreational outlets for their children and their children's friends in their own homes or in supervised recreational centers. The agencies and institutions now caring for neglected and delinquent children should not diminish their services, but should continue to function as actively as ever. Church and school authorities should work with parents and children in pointing out the dangers of unsupervised recreations. The children and adolescents should be encouraged to aid in the war effort in various ways, in salvage drives, as air raid messengers, doing Red Cross work, and the like.

We can learn a lesson from our English allies in this regard. In 1940 and 1941 there was a marked increase in juvenile delinquency in England, due to bombing and destruction of homes, the conscription of the fathers, the evacuation of children, etc. England realized the need of youth organizations to give children and youths a wide choice of activity. They organized farm clubs and a Youth Service Corps. The functions in this latter organization range from filling sandbags to collecting music for the navy and, according to a local New York paper, include activities such as cleaning first aid posts, filling bomb craters, running messages, sewing, collecting kitchen waste for farm animals, etc.

In this country a few sporadic attempts have been made to utilize the energies and drives of these children, but much more can be done. Children and adolescents need reassurance that they "belong" and that their efforts are appreciated. If we can give them constructive organized activities which will help in the war effort, we, like England, will soon see a drop in juvenile delinquency. The core of American civilization and power has been the home and its well-knit family life. Now, more than ever we must strive to preserve the family ties and keep our homes intact. In this way we will prevent juvenile delinquency and, at the same time, preserve our American way of life.

# PSYCHIATRIC ASPECTS OF JUVENILE DELINQUENCY

Frank J. Curran, M.D., New York City

UST what is juvenile delinquency? Is there a "crime wave" among our children and youths? Is the war producing an increase in criminality among children? These questions are troubling many of us. Articles printed in newspapers and magazines give conflicting information. In one periodical we read that juvenile delinquency has increased from 20 to 100 per cent in different sections of the United States, whereas in another article we are told that there is absolutely no cause for alarm about juvenile delinquency. Just what are the facts? What are the causes of juvenile delinquency? What can be done to prevent an increase in such delinquency? What can we, as members of the "home front," do to prevent the occurrence of delinquency in our children and in our neighbors' children?

A juvenile delinquent in New York State is a person over 7 and under 16 who commits an act or omission which, if committed by an adult, would be considered a crime or misdemeanor. Among the commonest types of juvenile delinquency are truancy, running away, stealing, disobedience, sex offenses, and destruction of property. In some states, the upper age for juveniles extends to 17, 18, or even to 21. In New York City there also exists an Adolescent Court which deals with boys between 16 and 19, and there is a corresponding Wayward Minors Court for girls. Although the adolescents sent to these two latter courts are not considered juvenile delinquents in a legal sense, yet they are often so considered from a social standpoint. Moreover, in the present war situation it is in the 16- and 17year-old group that delinquencies appear to be increasing both in number and severity.

Judge W. Bruce Cobb, Acting Presiding Justice. Domestic Relations Court, New York City, stated in a recent radio address that there was only a very moderate increase in juvenile delinquency in 1942 over 1941 and added: "In ordinary times it would have probably passed unnoticed." For the first three months of 1943, however, there has been an increase of over 30 per cent of delinquent children in the New York City Children's Courts. The largest increase

was in sexual involvement on the part of young girls. Judge Cobb further emphasizes the fact that there was no increase in the number of violent offenses. This latter observation substantiates my own observations of adolescent boys committed to Bellevue Hospital for mental observation. We have had, for example, no child under 16 in the adolescent ward in over a year who had killed another person, whereas in 1937 we had four such cases within a six months' period.

Mr. Patrick Shelly, the Chief Probation Officer of the New York City Magistrates' Courts, informs me that there was an actual decrease in the number of boys aged 16 to 19 admitted to the Adolescent Court in 1942 as compared to 1941. He believes this is due to the large number of boys aged 17 to 19 who join the Navy or Coast Guard. However, in the Wayward Minors Court between January 1 and May 24, 1942, there were 138 cases and in the same period in 1943 there were 214 cases, an increase of over 55 per cent. In 1942 the bulk of cases in the Wayward Minors Court was in the 16- and 17-yearold group. Similarly, in the Adolescent Court the largest number was in the 16- to 17-year age bracket, and there has been a tendency in this group for the crimes to increase in severity. Formerly there were many petty offenses, such as

stealing lead pipe from empty houses, whereas

now there are more burglary and grand larceny

charges. What are the causes of juvenile delinquency? From a psychiatric viewpoint we can say very definitely that psychoses or insanity and mental deficiency are responsible for only a very small percentage of Children's Court cases. Only a small portion of delinquents may be labeled as "incorrigible" or "habitual criminal" type, technically known as the C.P.I. or constitutionally psychopathic inferior group. Instead, the majority of delinquent children are delinquent because of their emotional and environmental problems. From 40 to 70 per cent of delinquents come from "broken homes" where parents are not living together or where one parent is dead or is in a mental hospital or prison. Even when both parents are in the home, there may be serious parental maladjustments. The parents may dislike each other and carry this resentment over in their attitude toward the children. Thus the children

Medicine.

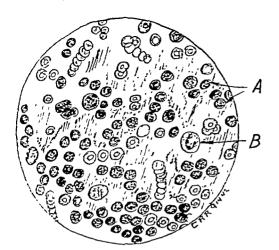

Fig. 1. Wright's Stain. A, Lymphocytes; B, Polymorphonuclear leukocytes.

The right lower extremity showed a 3 plus pitting edema from the ankle to about 4 inches below the knee; left ankle and dorsum of the left foot revealed 2 plus pitting edema. The upper extremities were normal except for epitrochlear lymphadenopathy.

Neurologic examination gave normal results. The lymphatic system superficially revealed marked lymphadenopathy in the cervical, axillary, epitrochlear, and inguinal regions bilaterally, with

no evidence of lymphadenitis.

The diagnostic impression at the time of physical examination was that we were dealing with a leukemia of the myelogenous type, because of the very great splenic enlargement and because, subsequently, it was determined that the total leukocyte count was tremendously increased to 1,272,000. That 99 per cent of these were lymphocytes was confirmed by thorough studies of peroxidase stained blood smears (Figs. 1 and 2). The following chart (Table 1) shows very clearly the results of the daily lematologic studies and constitutes the reason—the tremendous increase in leukocytes over and above the crythrocyte count—for my desire to have this case included in the literature.

TABLE 1

Amino acid—13.7 per cent
Total protein (P)—9.4 per cent
Total protein (S)—9.7 per cent
Albumin (P)—6.0 per cent
Albumin (S)—6.5 per cent
Fibrinogen—0.2 per cent
Globulin (P)—3.2 per cent
Globulin (S)—3.2 per cent

X-ray examination of the chest showed a more or less generalized hazy, feathery increase in the markings throughout the medial portions of both lower lung fields. There was also some evidence of bilateral thickening of the pleura. The cardiac shadow was increased in size and was droplet in shape. These changes were thought to be due to leukemic infiltration, with also the possibility of a chronic passive congestion. A flat plate of the abdomen revealed, on the left side, a large shadow extending from the level of the diaphragm to the left iliac crest, thought to represent the spleen.

It is interesting to note that because of the very marked leukocytosis and very marked anemia, it was almost impossible to obtain satisfactory precipitates for a completion of the blood chemistry.

Blood typing was also rendered extremely difficult, but it was finally decided that the weight of the evidence was definitely in favor of the patient's being a type IV. However, on cross-matching, agglutination was found, in some cases, with the patient's cells and the proposed donor's serum. The patient was, however, given a transfusion with type IV whole blood, which in the cross-matching revealed no agglutination with the patient's serum and the donor's cells and very slight agglutination with the patient's cells and the donor's serum. After 300 cc. of blood had been given, there was a slight reaction, during which the temperature rose from 100.6 to 102.2 F. and during which also he experienced mild chills. Transfusion was stopped at that time.

# Case Report

### CHRONIC LYMPHATIC LEUKEMIA—REPORT OF TWO CASES

CHARLES R. RICHARDSON, M.D., Clifton Springs, New York

CHRONIC lymphatic leukemia is a pathologic condition resulting from idiopathic hyperplasia of the lymphoid tissues. It is characterized by extensive proliferation of abnormal and immature nongranular, or lymphoid, types of cells, and their preponderance in the peripheral blood as determined by hematologic methods and the study of the bone marrow and fixed tissues. The cause is unknown, but it is placed with the malignancies.

Males are more frequently affected, and the disease is prone to occur in the later decades. There are also no proved predisposing factors. The cardinal signs and symptoms of leukemia are to be found namely, fatigue, enlarged lymph glands, splenomegaly, hepatomegaly, and an increased tendency to bleed, and, of course, the blood picture.

I present the first case as an outstanding example of lymphoid cell proliferation.

Case 1.-W. L., a white male aged 64 years, was admitted to the clinic on May 11, 1942, com-plaining of a sore throat and pain and swelling of the right lower leg. On questioning, he stated that he had been having frequent attacks of sore throat and "tonsillitis" during the winter months for at least five years; considering these simply as the sign of a simple "cold," he did not consult medical advice, but resorted to home remedies and self-medication. The relief obtained was definite but temporary. Each attack consisted of a severely sore throat, a feeling of fullness in the back of the throat, and was accompanied usually by a unilateral earache. During the preceding winter, these sore throats became somewhat more severe and more frequent, so that, urged by his son, he presented himself at the local hospital clinic for examination and advice concerning removal of his tonsils. These, according to his report, were found to be markedly enlarged and acutely inflamed. He was accordingly advised to resort to local symptomatic treatment until the inflammation subsided and then to report for tonsillectomy.

Local symptomatic treatment offered little relief, but the patient did not return to the hospital for further advice. About three to four weeks prior to this admission, he began feeling quite weak and finally became unable to do his farm work. Three days before coming to the clinic, he noticed that both ankles were quite swollen, the right somewhat more so than the left. He became aware also of pain in the right calf and ankle. At the insistence of his son, he was brought to the clinic for complete

The family history is not remarkable, nor is it at all contributory. The patient's past personal history is also not remarkable. The patient was unable to recall any childhood diseases, stating medical check-up. quite emphatically that he had never been sick

except for the frequent sore throats as described above.

Systemic review revealed that the patient experienced moderate chest oppression, amounting in certain instances to a dull pain, during a severe head "cold." This was described as just beneath the upper portion of the sternum. Prior to the present attack, the ankles had never been swollen. Interrogation concerning the gastrointestinal and the genitourinary systems revealed no abnormality of importance.

The reliability of the history as obtained from the patient and confirmed in essence by the patient's son may be questioned somewhat because of his poor command of English and because of mutual

interpretation difficulties. Physical examination on May 11, 1942, the day of admission, revealed a moderately alert, fairly well-developed, fairly well-nourished white male of about the stated age, appearing definitely pale and ashen and seemingly chronically ill. The skin was warm and dry and of normal texture. Hair distribution was of the normal male type; cranium was of normal contour and revealed no bony exostoses or other gross abnormalities. Eyes were normal in appearance, movement, and tension; pupils were equal and regular and reacted to light and accommodation. commodation; eyegrounds were not remarkable. Ears and nose showed no obstruction, bleeding, or discharge; there was definite pallor of the nasil mucous membranes. The tongue was slightly coated, the oral and pharyngeal mucosa were de-finitely role and the tongile man markedly byperfinitely pale, and the tonsils were markedly hypertrophied, pale, cryptic, and appeared chronically diseased. Dental hygiene was poor and the gums showed definite a live and the gums poor and the gums showed definite a live and the gums poor and showed definite pallor, but no bleeding, ulceration, or discoloration. Cervical lymph chains bilaterally were moderately enlarged and easily palpable. The thyroid was not palpable. Examination of the about revealed a normal content of the hory cape. chest revealed a normal contour of the bony cage with no gross abnormalities; tactile fremitus was normal; and the lungs were resonant throughout to percussion. Percussion also revealed slight enlargement of the mediastinal dullness both to the right and to the left of the sternum throughout its length. Breath and voice sounds were essentially normal. A few moist rales were heard over both bases posteriorly; there were no other rales, and no pleural friction rub. The heart was somewhat enlarged to percussion. Sounds were of fair quality, regularing the transfer of the property regular in rhythm, and the rate was 104 per minute, with no murmurs, no pericardial friction rub. Arteries showed marked beading.

The abdomen was markedly distended and tense; superficial veins were prominently distended, but not conforming to the caput medusae pattern; there was marked diastasis recti abdominis with evidence of a tumor mass at the upper pole, suggesting possibly herniation of omental tissues. The liver was palpable 1½ fingerbreadths below the right costal border, and the spleen was palpable in the left upper quadrant and in the left lower quadrant about 4 fingerbreadths below the level of the umbilicus.

No other masses or organs were palpable.

Read before the Neuron Club of Central New York, June 27, 1942.

# Federal Emergency Maternity and Infant Care Program in New York State

# A Report of the Council Committees of the Medical Society of the State of New York

THOSE responsible for the preparation of this article hope that the information herein will provide a better understanding of the Emergency Maternal and Infant Care Program<sup>1</sup> and will acquaint the medical profession with some of the difficulties which have arisen.

Congress made funds available in March, 1943,<sup>5</sup> and shortly thereafter (March 24–25) the Children's Bureau of the United States Department of Labor, which directs the program, conferred in Washington with the state and territorial health officers and their directors of maternal and child health programs for the purpose of presenting the Children's Bureau's plans to these officials and of discussing the Bureau's administrative regulations governing the use of the Federal appropriations for this purpose.

Immediately after returning from Washington, Dr. Edward S. Godfrey, Jr., State Commissioner of Health, requested a conference with the appropriate Committees of the Medical Society of the State of New York. The first meeting was

held on April 7, 1943.

Ten such conferences were held. These conferences were attended by the President, President-elect, Secretary, members of the Council Committees, and sometimes other officers of the Medical Society of the State of New York, the New York State Commissioner of Health and members of his staff, the New York City Commissioner of Health and members of his staff.

At one of these conferences held October 28, 1943, the Regional Chairmen in Obstetrics and Pediatrics of the Medical Society of the State of

New York<sup>3</sup> were present.

Four of these conferences were held before the New York State Department of Health submitted its first proposal on June 18, 1943, for an operating plan under the rules and regulations of the Children's Bureau. Discussions at the first four meetings were devoted largely to certain basic requirements of the plan proposed by the Children's Bureau. As a result of criticisms made by members of the conferences, the State Commissioner of Health made vigorous presentations to the Children's Bureau for changes in the plan. Although the members of the conferences were dissatisfied with several aspects of the program, there never was any objection to its objective; namely, to assure good maternity and infant care for the families of men in the armed services. This opinion was officially expressed by the House of Delegates of the American Medical Association, and has been repeatedly expressed by the officers of the Medical Society of the State of New York and in resolutions of many of its constituent county medical societies.

The Children's Bureau has made changes in the plan as a result of recommendations proposed at conferences of the Council Committees<sup>2</sup> and representatives of the New York State Department of Health. Efforts to obtain further desirable changes have by no means ceased.

There has been splendid cooperation between the official State agencies and the Medical Society of the State of New York in the development of the plan for the State of New York.

The following is a summary of the features of the program, as presented by the Children's Bureau, that received particular attention by the members of the conference and their disposition:

1. The requirement that payments be made directly to the physician or hospital rendering service.

It was the view of the Council Committees\* that this money should be given as a cash allotment directly to the service man's wife.

This opinion was presented to the Children's Bureau by the State Commissioner of Health on June 9, 1943. The Children's Bureau advised that such a procedure would be impossible under their interpretation of the intent of Congress. Accordingly, the State Commissioner of Health advised the Council Committees that this matter was beyond his control and should be taken up with Congress by the organized medical profession.

On September 22, 1943, an amendment to the act appropriating further funds for the Emergency Maternity and Infant Care Program, which would have provided a cash allotment rather than direct payments to physicians or hospitals, was proposed by Congressman Smith from Ohio. This amendment was overwhelmingly rejected.<sup>6</sup>

2. The provision of hospital care at the "ward cost per patient day" to be determined by a prearranged formula.

It was the opinion of the Council Committees that the use of ward facilities would tend to direct patients away from private care inasmuch as many hospitals, especially in the metropolitan New York area, would not permit private patients on their open wards.

<sup>\*</sup> The term "Council Committees" as herein and subsequently used shall mean the Council Committee on Public Health and Education and its subcommittees on Maternal Welfare and Child Welfare.

TABLE 2

Newtophilis   14.0   14.0   9.0   7	$\begin{array}{cccccccccccccccccccccccccccccccccccc$
-------------------------------------	--

Therapy was poorly supportive and x-ray therapy was refused by the patient. After the prognosis was discussed with members of the family, the patient was taken home and died twenty-two days after the day of admission. Postmortem was not obtained by the family doctor.

The second case, which was under observation at the same time, is of interest because of a coexistent bronchopneumonia, which responded to sulfonamide therapy.

Case 2.—E. V. M., a 67-year-old white woman, was admitted to the clinic on May 5, 1942, having been sent by a local physician. She had a history of a recent type III pneumococcus pneumonia with poor convalescence, during which she had been given 40 grains of sulfathiazole a day for three days in divided doses, then 30 grains a day in divided doses for two days. Cardiac failure had been present, for which the patient had been digitalized and placed on a maintenance dose of 1½ grains of digitalis daily.

Family and personal history were not remarkable except for the fact that the patient had had an extreme susceptibility to acute upper respiratory infection for a number of years.

Examination on admission revealed a well-developed, obese, white woman, acutely ill, moderately cyanotic, and semicomatose. Examination of the chest revealed numerous moist rales throughout both lung fields; definite evidence of consolidation at the left base was revealed on clinical and x-ray examinations. Blood count on admission revealed a leukocyte count of 32,400, with 82 per cent lymphocytes. A diagnosis on the day of admission was made and included: chronic lymphatic leu-

kemia, bronchopneumonia, and early cardiac failure.

On the night of admission, the temperature rose to 104.8 F., and the patient was moribund. At that time, she was given nasal oxygen and 6 Gm of sulfadiazine rectally. From that time on, the patient seemed to improve rapidly, and in four hours the temperature had dropped to 102 F. and the patient had roused from her stuporous condition. Sulfadiazine was continued in 1 Gm. doses orally thereafter, and the temperature curve rapidly leveled of at a normal reading. The sulfadiazine was continued for three days after the temperature had returned to normal. Blood studies were done daily, the results of which may be seen in Table 2.

Just before discharge, the patient was given a transfusion. At the time of discharge, the white blood count was still markedly elevated and measured 69,000 with 92.7 per cent lymphocytes. The discharge diagnosis, of course, was chronic lymphatic leukemia.

#### Discussion

The first case here presented is of interest, in my opinion, because of the extreme degree of lymphocytosis and the paucity of clinical symptoms until a few days prior to admission and, incidentally, up to a few weeks prior to death. The second case here presented is interesting because of the opportunity of observing effects of sulfadiazine, as used in the treatment of a coexisting pneumonitis due to mixed infection, on the definite chronic lymphatic leukemia which was present. The effect seemed to be little or none as regards the lymphoid cell proliferation. So far as the pneumonitis is concerned, however, the results were good.

### SIGN HERE, DOCTOR!

Additional fuel oil? Have your doctor sign... oh, it is gasoline you wish for a motor trip for your health. No matter—just have your doctor sign special form 3784x. Perhaps you are short on your vitamins, or orange juice doesn't agree with you?

Well, why don't you get a doctor's certificate and take it to your ration board so that you may get more red points for meat, or blue points for canned pineapple juice? You're tired and would like a rest? Didn't you know that you can get sickness insurance benefits while you are out ill? All you

need is a certificate from your doctor. Or perhaps your job doesn't agree with you when you know you can get more money elsewhere. In that case you can get clearance if you show your present work is injurious to your health. Get a certificate from your doctor. What do you mean you can't get a certificate from your doctor? Do you mean to say that he has enlisted in the Army and is with the forces invading Sicily? He can't do that to you. Your health is important, and besides you have got to get a doctor's signature these days to get anything—Editorial in Rhode Island, M. J.

The following are examples of matters now pending:

1. The initial plan of the Children's Bureau urges the importance of infant health supervision but in so doing provides that it must be rendered through approved child health conferences or wellbaby clinics where they exist and are available without a so-called "means test." Where such are not available such supervision can be given under the plan only by a pediatrician or physician meeting special qualifications in this field.

While the Council Committees and the State Commissioner of Health were thoroughly in accord with the inclusion of provisions for health supervision, they felt that the regulations were impractical and unreasonable in that they did not permit the patient the choice of a child health conference or a private physician, nor did they make a reasonable provision for the general practitioner who may deliver the baby and take care of it while it is sick but not supervise it while it is well.

These objections were presented by the State Commissioner of Health and other persons and groups,8 and early revision of the present policies is anticipated so that health supervision may be established on a more reasonable and workable basis.

2. The Children's Bureau has interpreted the appropriation as intended to cover all medical care required by the expectant mother throughout her pregnancy and for six weeks thereafter. In this interpretation it has stated that the fee for complete maternity care or the fees for such additional consultant services as may be indicated shall cover all necessary medical care during said period.

The Council Committees and the State Commissioner of Health believe that this policy is unreasonable and will be changed in favor of fairer definition of the types and extent of illnesses which the physician is called upon to care for under the fee for complete maternity care.

3. Criticism by the practicing physicians of the various forms and statements which the State Department of Health has required in the operation of this plan.

At the request of the State Commissioner of Health, the President of the Medical Society of the State of New York appointed a committee of two obstetricians and one physician in general practice, to advise with the Commissioner on the revision and simplification of these preliminary

The Commissioner has told the Council Committees that the revision is completed and that

simplified forms have resulted which should reduce to a minimum the complexity of this particular phase of the program.

In presenting this review, the Council Committees desire to emphasize the following: First, there has been the closest cooperation between the State Commissioner of Health, representatives of the Medical Society of the State of New York, the Commissioner of Health of New York City, and many other interested medical groups. They have worked and will continue to work cooperatively in an attempt to bring about other desirable adjustments with the Children's Bureau. Second, the Children's Bureau has given assurance that this program has been developed strictly for the purpose of meeting an emergency for the duration of the war and six months thereafter. Third, while many of the problems that were presented have not been entirely resolved, progress has been made and efforts are being continued.

The Council Committees believe that all reasonable efforts are being made by them and the State Commissioner of Health in the interests of the patients and the medical profession. They believe that the majority of physicians in New York State appreciate the need of cooperation in a program of such wartime importance. They also believe that with or without an E.M.I.C. program, the obstetric and pediatric care of the wives and infants of service men will be well provided by the medical profession.

<sup>1</sup> A summary statement of the provisions of this program

as it now operates appears on page 298 of this issue.

<sup>7</sup> J.A.M.A. 123: 1125 (Dec. 25) 1943.

Notably, District Number I (upstate New York) of the American Academy of Pediatrics, the American Academy of Pediatrics, and the conference group called by the Children's Bureau in Washington on December 10 and 11, 1943.

Advisory Committee on E.M.I.C. forms to the State Commissioner of Health: Dr. George W. Kosmak, Dr. James K. Quigley, and Dr. Herbert E. Wells.

Preliminary inquiry indicated that the hospitals for the most part were either unable or reluctant to change this rule. In consequence, the program was modified in New York State so as to require that, with the exception of certain teaching hospitals, care must be provided in "small private wards or in semiprivate accommodations," thus permitting the desired relationship between patient and private physician to continue.

This change was accepted by the Children's Bureau.

Subsequent experience showed it to be impractical because of insufficient semiprivate or smallward facilities. The plan was, therefore, further modified to permit ward care of private patients and, in general, the hospitals have found the means of making this possible.

3. Provisions for remuneration of physicians.

It was the opinion of the Council Committees that the compensation provided for maternal care was low in comparison to that usually received by physicians in New York State for such services.

The State Commissioner of Health obtained the consent of the Children's Bureau for an increase in the remuneration. Similarly, the amount available for the care of a sick infant was increased.

4. The plan provides for additional fees where the services of a qualified consultant are required but makes no provision for recognizing the extra services of a qualified obstetrician or pediatrician where such physician has undertaken the basic maternity or sick infant care of a patient under the plan.

In other words, if an obstetrician accepts a maternity case he must provide all care related to the pregnancy, including the care of major obstetric complications, for the fixed fee, whereas, if the basic maternity care is given by a general practitioner at the same fee, he is not expected to care for major complications and may call upon a qualified specialist, to whom a separate fee is paid.

The Council Committees believe that some system should be devised for recognition of the extra services of the qualified specialist and for compensating him in keeping with the extra services rendered.

The State Commissioner of Health recommended to the Children's Bureau that a differential rate be established in recognition of the services of qualified specialists. The Children's Bureau expressed itself as sympathetic to this request but in view of the fact that Congress has already questioned the maximum fees it was allowing, it felt that it was not in a position to recommend such a plan at present.

5. Fees paid under the plan must be the only compensation received for the services authorized under the plan. This regulation provides that the payments to the hospitals or physicians by the State Department of Health cannot be used as a means of part payment for more luxurious hospital accommodations than those offered under the plan, nor can the patient pay the physician a supplementary fee regardless of her possible ability and desire to do so.

The Council Committees believe that in view of the failure to have the available funds paid directly as a cash allotment, an alternative would be to allow the funds available to be paid directly to the physician or hospital as complete or partial payment for the services rendered in accordance with the patient's own arrangements with the

physician and hospital.

The Commissioner of Health presented this request to the Children's Bureau. The Children's Bureau did not feel that such a regulation was within the purpose of the appropriations and,

therefore, could not accept it.

This matter was discussed in Congress rather inadequately, and passed over without serious consideration. It was recently taken up at a conference between the Children's Bureau, the official representatives of the American Medical Association, American Hospital Association, and other groups and organizations concerned. The expressed concensus of this group was in opposition to such a proposal.

6. Initial plan that care given preceding date of authorization of the formal application for care

could not be paid for under the plan.

The Council Committees and the State Commissioner of Health objected strenuously to these limitations on the ground that they set the necessary administrative procedures above the actual intent of the appropriation, and the initial plan for New York State submitted to the Children's Bureau made broad provisions for retroactive approvals to provide care for those eligible from the first of April, 1943.

The Children's Bureau was sympathetic to the purpose of this request but for administrative reasons could not see fit to grant it. However, a few concessions were allowed in the interest of lessening the injustices that might arise through misunderstanding in the early days of the pro-

The New York State plan was finally put into effect on July 1, 1943.

At the later conferences many details of the plan and several major issues which had not been previously presented to the Children's Bureau have been discussed and further adjustments in the plan are anticipated.

F. Hospitalization may be provided the prospective mother at any time after original authorization up to six weeks after delivery for any illness requiring such hospitalization and for the infant during its first year of life, provided medical care has been authorized under the plan or is otherwise provided at no cost to the patient or her family. The individual hospital is free to determine the type of accommodations it can offer patients under the plan. The per diem rate allowable is determined on the basis of hospital costs calculated in accordance with the Children's Bureau formula and is intended to include all the extra services usually required, such as delivery room, anesthesia, laboratory service, and medications.

G. Complete medical and hospital care may be provided through the clinics and on the wards (under staff care) in hospitals operating services approved for internships, or residencies in obstetrics or pediatrics by the Council on Hospitals and Medical Education of the American Medical Association, provided the patient elects to receive such care. In such cases, the hospital may receive a fee not to exceed \$1.50 per clinic visit up to a total of ten visits, but may make no charge over and above its per diem ward rate, as established under the Children's Bureau formula, for medical services rendered while the patient is in the hospital.

H. Other services available:

;٠

6.000

ر د د ا

¢,

1. Bedside nursing care by a registered nurse may be authorized in home or hospital for acutely ill patients requiring it and will be reimbursed at locally accepted rates.

Visiting nursing service should be employed whenever it is available through a health agency and at no cost to the patient, and patients under the plan will be referred routinely to the attention of such agency. Otherwise, visiting nurse service may be authorized, upon application, at rates agreed upon between the State Department of Health and approved agencies for routine delivery care and otherwise as required.

3. Emergency medical assistance to the attending physician at home delivery may be authorized and will be reimbursed at the home visit rate of \$3; medical assistance at an operation performed by a consultant may be authorized at the rate of \$10 (provided qualified interns or residents are not available for this purpose).

Anesthesia. No provision is allowed for an anesthetic fee in the case of a normal home delivery other than as described above in item 3, nor for hospital deliveries, whether normal or operative, where the hospital enters fees for anesthetists in its statement of operating costs. Where the hospital does not do so and a trained intern is not available, a competent physician may administer the anesthetic and receive reimbursement as a medical assistant, as stated in item 3 above, excepting that in normal deliveries he can receive only the hospital visit rate of \$2.\* If, however, the delivery or other procedure is operative, he may receive a fee of S10.

5. Blood or plasma for transfusion may be purchased at the local prevailing rates for ward patients.

6. Ambulance service may be employed when indicated at the local prevailing rates.

7. Unusually expensive drugs may be provided under the plan, provided they are essential and are included in a list of such drugs to be established by the Commissioner of Health with the advice of a competent advisory committee.

Unusually expensive laboratory tests may be provided under conditions as above stated in item 7.

Services at present not provided:

1. No provision is made to reimburse physicians for circumcision performed during the lying-in period unless it is performed for medical reasons. In such circumstance, an application for care of a sick infant is required and a fee of S5 allowed.

2. No special provision is made for a fee for care of the newborn infant during the first two weeks of hospitalization of the mother. Applications for pediatric health supervision may, however, be made at once and such care may start immediately after birth. Prematurity constitutes a basis for application for care of a sick infant.

3. No provision is made for dental care under this plan.

#### Procedures in Connection with Ap-III. plication

A. Application forms can be obtained from the district state health officer. They may be obtained at local Red Cross chapters, cooperating hospitals, or other agencies designated by the district state health officer.

B. Responsibility for seeing that the application is completed and mailed to the district state health officer rests with the applicant.

 C. Delayed application may result in inability of the State Department of Health to authorize reimbursement, since the date of signature of the applicant determines the date on which authorization can commence. The effective date is the date of signature for maternity care and not more

<sup>\*</sup> Pending attempts to establish a fee of \$5 under this plan as approved by the Children's Bureau of the United States Department of Labor.

# Summary Statement of the Federal Emergency Maternity and Infant Care Program—New York State Plan

## New York State Department of Health, Albany, New York

THE New York State Plan for the Federal Emergency Maternity and Infant Care Program has been promulgated under the administrative instructions of the Children's Bureau of the United States Department of Labor acting under the authority of Congress.

The object of the plan is to provide payment for maternity care (medical and hospital) for the wives and all necessary medical and hospital care for the infants under one year of age of service

men in pay grades 4, 5, 6, and 7.

### I. Eligibility

The husband or father must be in pay grade 4, 5, 6, or 7 of the Army, Navy, Marines, or Coast Guard (living, missing in action, or deceased) at the time of application.

Where adequate facilities are offered by the Army or Navy, or through a health department service, such services must be utilized in so far as they are able to meet the needs of the patient.

# II. Care and Fees Allowable Under the Plan

A. The Children's Bureau requires that the physician, hospital, individual, or agency rendering any service authorized for payment under this plan agree not to charge or accept any remuneration for such service than through the State Department of Health as herein provided.

Authorization for basic medical care (maternity or infant care) under the plan is a requisite to authorization for any of the other services described below (sections II-D to II-H) unless such basic medical care is supplied (at no cost to the patient) either through an insurance plan or gratuitously.

B. Complete maternity care:

For complete maternity care defined as including at least five prenatal visits, made on or subsequent to the effective date of authorization, delivery, and postpartum care, including final examination of mother and newborn infant at approximately six weeks, a fee of \$50 will be allowed. If less than five prenatal visits are made during the period of authorized care (i.e., commencing with the date of applicant's signature—see section III-C) deductions of \$3 will be made for each visit less than five. Similarly, if the patient is discharged from care prior to five weeks after delivery, full payment for complete obstetric care cannot be given. If service is divided, a maximum of \$15 will be allowed for pre-

natal care, \$35 for delivery and complete postpartum care, and \$10 for complete postpartum care only, or, if not complete, at the rates for a house or hospital visit as specified below (item C-1) but not to exceed a total of \$10.

- C. Medical care of infant during first year of life:
  - 1. For acute illness, care may be authorized for a period not in excess of three weeks (renewal of authorization is required for cases of longer duration). A limit of \$24 in fees is allowed per authorization on the basis of \$3 per house visit and \$2 per office or hospital visit, with the further provision that the fees during the first week of illness cannot exceed \$12, and for any subsequent week of the same illness, \$6 each week.
  - 2. Pediatric health supervision by a qualified pediatrician or a physician who has had special training in pediatric health supervision may be authorized for the purpose of advising on feeding, observing and guiding development, and giving immunizations for well infants under one year of age at \$2 per office visit to a total of \$18 (or nine visits). It is at present required, however, that where adequate child health conferences or well-baby clinics are available at no cost to the patient and without the application of a means test, such clinics must be used.
- D. Consultation services by qualified specialists may be authorized for patients under maternity or sick infant care whenever there is reasonable indication. Such services, where no operation is performed by the consultant, will be reimbursed at the rate of \$15 for the first visit in the home or \$10 for the first in office or hospital, and \$10 for subsequent home or \$5 for subsequent office or hospital visits. A single authorization will allow up to three visits. Where an operation is performed by the consultant, reimbursement will be on the basis of a fee schedule to be established (as nearly comparable to the Workmen's Compensation Schedule as is possible). The operative fee shall include the diagnostic visit and necessary postoperative visits, but may in no instance exceed a total of \$50.
- E. Consultation services for intercurrent illness during pregnancy or six weeks thereafter when the illness is such as to jeopardize life or the continued health of the patient or her infant (see

consultant services).

sioner of Health will ask each county medical Society to canvass the physicians in their county and to supply him with a list of physicians who desire and, in the opinion of the Society, are qualified to participate. Physicians who are qualified will then be duly notified and every effort will be made by the Department not only to keep them currently informed of the conditions of the plan, but also to continue its effort in bringing about further adjustments in the plan that would be advantageous to the patient, physician, and others participating.

#### THE PUBLIC'S FOOT

One of the difficulties in getting people to take action in any given direction is that human beings are almost certain to miss the significance of a simple declarative sentence, or of a routine happening. To catch attention there must be some emphasis by tone or inflection or accent or play on words, or some drama or association, or climax. In contrast to a flat declaration, consider the statement that "An army marches on its stomach." Here there is association between this truth in metaphor and the somewhat ridiculous mental picture that it creates. From this association comes remembrance, and remembering, one ponders. But if the statement is "The public walks on its feet," or if the observer notes that this is so, the listener or reader or observer is unimpressed. The information obtained is not news, nor is it dramatically presented. It appeals neither to the esthetic nor the intellectual and it fails to arouse either sympathy or after-

Even if "The public walks on its feet" is an unimpressive statement, the fact that man does so walk, rather than on feet and hands, has created a far-reaching public health problem. For though structurally and functionally the foot is an amazing mechanism, it is not yet completely adapted to the erect posture. Nor is the bony skeleton of one person's feet so exactly like another's, or the amount and distribution of downward pressure so much the same that, proper width and breadth assured, the ordinary stock shoes are suitable for all people. The net result of these various contributing factors is foot trouble for a large proportion of the public, just what proportion it is hard to say. No hard, cold, reliable data are available on this point, but common observation indicates that more than a majority of adults have one or another kind of foot pain, weakness, or impairment. If this were not so, bedroom slippers would not always be shown in pictures of the tired business man, relaxed at home. And if uncomfortable feet were not a part of woman's cross, there would be lots less pawing around for

shoes in the dark of the moving picture theater.

It may fairly be said, then, that foot discomfort and partial disability are relatively highly prevalent. At the same time it must be confessed that there are few places to which the foot sufferer may turn with any assurance of relief. Foot troubles do not kill, nor are they as a rule completely disabling, and the medical profession and public health workers are not inclined to give much thought to a disability which does neither of these things. Apparently the subject is beneath the notice of the high-powered orthopaedist, and he will have none of it. Give him something that involves fractures, stiff joints, deforming that a subject the subject in the subject to the formities, plaster casts, and the adjustments of muscles, and he is your man; but go to the same orthopaedist with nothing more serious, from his standpoint, than a callus, and he is not likely to be interested, and not assuredly competent. The average physician, for his part, lacks fundamental knowledge as to the complicated functional anatomy of the foot. He is not, therefore, in position to bring relief to the patient, and ends up by referring her or him to a shoe store or a chiropodist. This is not to suggest that physicians undertake the routine trimming of toenails or the cutting of corns. But it does seem worth emphasizing that pedal disabilities constitute a vast problem and a correspondingly vast demand for relief, and that since the medical pro-fession is not meeting this demand, these sufferers are seeking aid and comfort in other directions. They thus create public support and, in some instances, legislative backing of those who, from the medical standpoint, must be regarded as irregulars and subprofessional, and therefore not a group to be encouraged. And, more important from the sufferer's standpoint, he gets only temporary relief, as a rule.

Another deterrent to serious consideration of the foot is that at its best, and even with red toenails, it is not a thing of which poets often write: of the ankle (female), yes; of the curve of the calf (female), higher and higher praise; but of the foot, male or female, no. This is understandable, for to the casual observer, the foot is but a slewed-out, battercakelike extremity, with over-riding toes and a strong tendency to corns, calluses, and bunions. And so to the world at large the foot is not an inspiring subject and, unlike syphilis, has not been adopted by fashionable society as a drawing room topic. Each dowager and smart young matron tends to regard her own foot pains as personal, a bit on the vulgar side. Obviously, if the woman of leisure does not feel that this is a dilemma from which she must deliver her lesser sisters, the lesser sisters must continue to suffer surreptitiously, and so with the butcher, the baker, and the policeman on his beat. Not until these foot sufferers become as vocal and clamorous and objectionable as a militant minority, though they are not a minority, will the medical profession be moved to find an answer.

In spite of all these things, a few physicians have undertaken serious study of the comparative anatomy of the foot, of its evolution, its mechanics, of the effect of the erect posture, and the pull of gravity on and through the foot. As nearly as can be gathered, these men have established relatively simple diagnostic procedures and quite effective therapy. Apparently, however, their pleas that the medical profession adopt a different attitude in regard to foot troubles, that it inform itself, and that it exercise modern diagnosis and therapy have fallen on deaf ears. And the suggestion that foot troubles constitute a public health problem is likely to strike horror in the hearts of the virus worker, the nutritionist, the administrator, the epidemiologist, unless they happen themselves to have some personal experiences along this line. But let it not be forgotten that the high incidence of a minor and lowly disability may constitute a more serious public health problem than does some aristocratic but comparatively rare disease.—Editorial in Am. J. Pub. Health

than seven days prior to the date of signature for sick infant care or two days for emergency care.

- D. The patient has free choice of her physician and hospital provided the physician and hospital are willing to accept patients under the provisions of the Emergency Maternity and Infant Care Plan.
- E. Emergency care may be rendered patients eligible under this plan and authorization subsequently obtained provided application is made within two days (Sundays and holidays excepted). Such application must be made for basic medical care (maternity or sick infant) or hospitalization and for nursing service of more than forty-eight hours' duration. Authorization of the other services allowable, such as consultation, medical assistance, emergency nursing for less than forty-eight hours, ambulance or other special services, may be requested at the time of submitting the statement of services rendered. If, however, the physician or hospital administrator prefers the assurance of authorization for payment before that time, it may be obtained by a telephone request to the district state health officer.
  - F. Procedures to be followed by physician:
  - 1. He may wish to advise eligible patients of plan and where they may obtain application forms.
  - 2. He should verify the husband's or father's rank from the family allowance card or a letter (verification is required by regulations of the Children's Bureau).
  - 3. He should discuss the hospital to be used and advise patient to make prompt application to the hospital so that her hospital application also may be filed early and arrangements for care reasonably assured in advance of delivery.
  - 4. Within two weeks of mailing the application to the district state health officer, the physician and patient each should receive notification of the action taken. If this is not received, he may wish to make inquiry of the district state health officer.
  - 5. Upon completion of the service authorized, the physician should complete the "Statement of Services Rendered" which will be sent him with the authorization notice and send it to the district state health officer. The regular State voucher for payment required by the State Comptroller will thereupon be made out for the physician's signature and sent him by the Central Office of the State Payment of the Department of Health. amount stated on the voucher will usually be made within four weeks of the date of its return to the State Department of Health. If for any reason the physician cannot be paid in full, the matter will be explained to him.

## IV. Standards of Care

A. The conditions of the New York State Plan, as approved by the Children's Bureau, require that prenatal and delivery care be given in accordance with accepted standards of good obstetric practice, as outlined in the circular "Standards of Prenatal Care" issued by the Children's Bureau (publication No. 153\*). Physicians participating in the plan are required to supply care meeting at least with this minimum.

B. The conditions of the plan, as approved, require that hospitals accepting patients under the plan must meet the "Minimal Requirements for Approval of Hospitals and Maternity Homes" issued by the Children's Bureau on March 30, 1943. Ability to so qualify shall be determined after inspection by the State Department of Health.

## V. Qualifications of Physicians

A. Maternity or sick infant care under the plan may be given by any doctor of medicine who is licensed to practice in New York State and who is a graduate of a medical school approved (at the time of graduation or since) by the Council on Hospital and Medical Education of the American Medical Association. Physicians who do not meet these qualifications, but who have had training or experience of such a nature as to qualify them, may make application to the Commissioner of Health through their county medical society for approval as a participating physician.

B. Consultant services may be rendered by specialists in the appropriate field who are diplomates of a specialty board. Other physicians who have, in the opinion of their county medical society, equal qualifications may be recognized as such upon application to the Commissioner of Health who shall act with the advice of a qualified advisory committee.

C. Pediatric health supervision can, under the present conditions of the plan, be given only by a qualified pediatrician or a physician who devotes a major part of his practice to pediatrics or who has had special training in pediatric health supervision. The Department has submitted to the Children's Bureau a request to permit such care by any physician as qualified under item A above, for a period of one year, during which time opportunity will be afforded for all physicians who desire to do so to attend a brief qualifying refresher course in this subject.

D. To facilitate the establishing of registers of qualified men as above stated, the Commis-

<sup>\*</sup> Copies of this are being sent to all physicians participating in the program. Additional copies may be obtained upon request of the district state health officer.

# Postgraduate Medical Education

Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York are published in this section of the Journal. The members of the committee are Oliver W. H. Mitchell, M.D., Chairman (428 Greenwood Place, Syracuse); George Baehr, M.D., and Charles D. Post, M.D.

## Laboratory Tests and Methods in Medicine

A SINGLE lecture on general medicine was given before the Suffolk County Medical Society at Link's Old Oak Hotel, Patchogue, at 12 m. on Wednesday, January 26, 1944.

The title of the lecture was "The Significance

of Laboratory Tests and Methods in the Practice of Medicine." The speaker was Dr. Ralph G. Stillman, assistant professor of medicine (clinical pathology) at Cornell University Medical College in New York City.

## "Rheumatic Fever-Rheumatic Heart Disease"

A LECTURE entitled "Rheumatic Fever—Rheumatic Heart Disease" was delivered by Dr. J. G. Fred Hiss before the St. Lawrence County Medical Society at 12 o'clock noon on January 20 at the Potsdam Club in Potsdam.

Dr. Hiss is professor of clinical medicine at Syracuse University College of Medicine. The instruction was presented as a cooperative endeavor between the Medical Society of the State of New York and the State Department of Health.

### THE MARRIED LIVE LONGER

The chances of survival are greater for the married than for the single, much more so among men than among women. Not only does marriage select the healthier lives, but it also creates a more healthful environment. The marked advantage of married men over bachelors in respect to mortality persists throughout life, and is greatest at ages from 30 to 44 years, the period during which they are raising their families. At these ages the death rates among the married men are just about half those for the single. This is based upon the experience of the general population in New York State, exclusive of New York City, for the period 1939–1941. Although the relative advantage of the married men over the bachelors decreases progressively with age, it still amounts to almost 25 per cent at ages from 65 to 69 years. Among women, the single are at their relatively greatest disadvantage in mortality during their 30's, and here the differential is only one-quarter.

In the broad age period from 40 to 74 years, spinsters and married women have practically identical

death rates in this experience.

The current situation differs in several respects from that of only a decade ago. Between 1929–1931 and 1939–1941 the death rates declined somewhat more rapidly among the married than among the single at ages under 40. The effect of this has been to add to the relative advantage of the married at these ages. The difference in trend has been very slight among men, the decrease in the death rate at ages 20 to 39 being 38.8 per cent for the single and 39.4 per cent for the married; for women the corresponding declines were 35.7 per cent and 46.8 per cent. The greater relative gain among married women is undoubtedly due in large measure

to the marked improvement in mortality from the conditions incidental to childbearing. At ages 40 or over, the single have experienced the sharper decline in mortality, with the result that the disparity in mortality between the two groups has been reduced.

While the married have a distinct advantage over the single as regards mortality, those whose marriages are broken by death experience a mortality even higher than those who remain single. The largest difference in mortality is found between the widowed and the married. For example, at ages 20 to 44, widowers have death rates from two to four times those for married men; widows at these ages experience rates from one and one-third to twice the rates of married women. The relative improvement in the mortality of widowers during the last decade fell below the records made by either the single or the married, thus widening the gap in death rates between widowers and the other two groups. The picture is not so clear-cut in the case of women.

Obviously, marriage is a stabilizing influence in the life and health of the individual. That it is much more so for men than for women may reflect the fact that women, whether married or single, live fairly sheltered lives. Among men, however, the unmarried are more apt to take greater chances with their health and are less likely to be adequately cared for in case of illness. Another factor is that marriage is a somewhat more selective process for men than for women. The head of the family must at least be well enough to work for a living, whereas women, even if below par in health, can often manage somehow to take care of the home.—Statistical Bulletin, Metropolitan Life Insurance

### BETTER FAMILY DOCTORS

Some interesting observations made by Brig. Gen. David H. W. Grant, the Air Surgeon, United States Army Air Forces, were recently reported in the press. General Grant is quoted as stating that the family doctor is "coming back" after the

Speaking specifically of flight surgeons, he says that even though they are specialists, they are required to attend all the medical needs of individuals under their care. In this way they are being well prepared to do general practice, in which preventive medicine will have an important part. The flight

surgeon must be alert for signs of fatigue, emotional upsets, and organic disease of men flying our planes. In other words, his job is to keep them fit so as to

"keep 'em flying."
Rear Admiral Ross T. McIntire, Surgeon General of the United States Navy, in addressing the 15th Annual Scientific Assembly on October 2, also emphasized the fact that physicians returning from military service to civilian practice will apply preventive medicine to a much greater degree than has been done in the past.—Editorial in Med. #### EXPERIMENTS WITH TUBERCULOSIS VACCINE

The tubercle bacillus can survive desiccation. Hermetically sealed in glass capsules containing less than one billionth of an atmosphere, the bacillus survived more than one year at body temperature. In this experiment the bacillus was very dry, which may have contributed to its dormancy. Incubated in a partial vacuum, saturated with water vapor, but deprived of oxygen, the bacillus lost all power of growth, even when introduced into the most highly susceptible animal body. The bacillus, so to speak, was asphyxiated, but without loss of antigenic action, as revealed by immunizing animals with avian and human strains of asphyxiated tubercle bacilli.

Preparation of a nonviable asphyxiated tuberculosis vaccine with immunizing power allegedly
superior for laboratory animals to other products is
reported by Potter of the Laboratory of Preventive
Medicine, University of Chicago. Numerous investigators have attempted to obtain a relatively
undenatured tuberculosis vaccine by storing dry
tubercle bacilli at refrigerator temperatures in the
maximum vacuum obtainable with a high grade
mercury pump. Such stored bacilli remain alive
and fully infective for at least two years, presumably because of a nearly complete metabolic standstill caused by absence of moisture and warmth.
In order to kill the bacilli by lack of oxygen, Potter
therefore repeated the tests under conditions that
maintained normal moisture and optimal temperature.

Highly virulent human tubercle bacilli were placed in empty pyrex test tubes together with 0.5 cc. of freshly boiled tap water. The oxygen was then removed in three stages, first by prolonged evacuation with a Hyvac pump, by which the estimated oxygen pressure was reduced to a two-hundredth part of that of the original air. Second, the evacuated tubes were filled and re-xhausted seven times with electrolytic hydrogen, after which lavage only a hundred-thousandth part of the original oxygen remained in the tubes. Finally the residual traces of oxygen and hydrogen were absorbed on powdered palladium sponge. The tubes were then stored in the dark at 38 C.

All organisms from tubes thus prepared and opened between the twentieth and forty-second day

of storage failed to grow when plated on a variety of favorable culture mediums. Five to 10 guineapigs were injected subcutaneously with each asphyxiated sample. Guineapigs injected with the twenty to twenty-five day asphyxiated cultures occasionally developed tuberculosis. All guineapigs injected with cultures asphyxiated for at least thirty days showed no evidence of tuberculosis when killed eight weeks later. Similar results were obtained with asphyxiated highly virulent bovine and avian strains, 6-week old chicks being used as the test animal.

Since tubercle bacilli killed by asphyxiation are presumably less denatured than bacilli killed by heat or chemical antiseptics, it would seem reasonable to hope that asphyxiated vaccines would have immunizing powers superior to those of any other nonviable tuberculosis vaccine thus far tested. A series of rabbits and pigeons were therefore given five subcutaneous injections at five-day intervals of asphyxiated avian tubercle bacilli. The pigeons continued well for seven and one-half months, at which time they were killed, necropsies revealing almost complete disintegration and absorption of the injected vaccine, without active tuberculosis. The rabbits were killed from one year to seventeen months after vaccination, at which time they were also without signs of tuberculosis.

Beginning at four and one-half months after this vaccination, groups of rabbits with an equal number of nonvaccinated controls were tested for acquired immunity by intravenous injection of massive test doses of living avian tubercle bacilli. The vaccinated rabbits developed but one-sixth as many lesions as the controls, and by the end of fifteen months had shown but one-fourth their tuberculosis morality. This degree of postvaccinal immunity is apparently superior to that reported by Opie and Freund following vaccination with heat-killed tubercle bacilli. Potter's tests show that an appreciable degree of the postvaccinal immunity persists for at least a year, with full duration not yet determined. Attempts to improve the nonviable tuberculosis vaccine by adopting methods that would facilitate more rapid interstitial disintegration and absorption of the injected asphyxiated bacilli are now in progress.

—J.A.M.A.

# Medical Legislation

(Bulletin No. 1 issued by the Legislative Bureau of the Medical Society of the State of New York, January 11, 1944)

GREETINGS for the new year! We welcome the opportunity of joining hands with those who have worked with us in previous years and we also welcome the cooperation of the others who for the first time will take over the responsibility of legisla-

tive work.

To those of you who were not fortunate enough to attend the conference of County Society Legislative Chairmen, which was held on December 7 in Albany, we report that on that occasion we discussed the medical features of the Wagner-Murray-Dingell bill. We had Dr. Louis Bauer, chairman of the American Medical Association's Council on Medical Service and Public Relations, outline to us the program of activities which that Council is pledged to carry out during the next year, which, we understand, expects assistance from the county society legislative committees. It will from time to time submit information of things happening in Washington and propose ways in which we can assist him. This is a new activity on the part of the A.M.A., the need of which has been felt for some time.

The Wagner-Murray-Dingell bill, which is the most important measure in Washington at present, is with the Finance Committee in each House. There is no indication that either committee will begin its study very soon. When they do take it up it will, without doubt, be by a subcommittee which will endeavor to secure expressions of opinion as to the relative merits of its sections by conducting a number of hearings in Washington and probably in other sections of the United States. As was pointed out on a previous occasion, the bill is in the nature of an omnibus. Many of its features are already the law of the land. The principal objective of the bill is to unify in a federal measure what already exists in many states and to extend some of the features in some instances. But the medical section is new and it is to this that we especially direct our attention. If you are not clear as to the objectionable features of the bill, we shall be glad to give you the benefit of our study and experience; and, likewise, if you would like to have somebody discuss the bill before your county society, we shall endeavor to assist you on that score. A number of the county society auxiliaries, directed by Mrs. Madden, the State Legislative Chairman, are very helpfully arranging public meetings where the Wagner-Murray-Dingell bill is discussed.

We anticipate a very busy year. The Albany session may be short but it will be, without doubt, fruitful. The Governor has suggested in his introductory message the appointment of a commission to investigate the subject of medical care. There is a commission studying the manner in which the Workmen's Compensation Law is operating. Another commission is studying the condition of the mental hygiene hospitals. The Mailler Long-Range Health Commission is still working, and from some of these we can expect proposed legislation. There will be bills introduced affecting the training and registration of nurses, which may be of vital importance to the physicians.

The chiropractic committee created by the last

Legislature has held a series of hearings and is engaged in preparing a report which it will submit to the Legislature some time next month.

Care of the returning disabled soldiers may

necessitate additional legislation.

All of these things will be considered in the next three months and, in addition, there is an equal number of matters that will come before Congress which will be of equal importance.

We hope that all of the societies have appointed willing workers who will have the time and embrace the opportunity to work with us enthusiastically.

The Assembly has announced its committees and we are listing below the personnel of these with which we usually work. You will find that there are very few changes. The Senate committees will accompany the next bulletin.

#### Bills Introduced

Senate Int. 9—Wicks, creates in the State Education Department a board for licensing and regulating the practice of optical dispensing and appropriates \$10,000. Referred to the Finance Committee.

Assembly Int. 12—Bennison, provides that lien of a hospital on suits, claims, or demands of a person admitted thereto shall be exclusive of personal services rendered by physician or surgeon. Referred to the Judiciary Committee.

Assembly Int. 63—Wright, provides that no State Regent shall be elected to succeed himself unless his previous term of office shall have been less than 5 years. Referred to the Education Committee.

in Chapter III, Article VI, of the By-Laws of the Bronx County Medical Society; and be it

"Further resolved: That at the termination of the period of emergency as determined by the society, this fund be known as the general fund of the Bronx County Medical Society, to be used for purposes beneficial to the society as determined by two-third vote of the membership pres-

ent at any society meeting; and be it "Further resolved: That the accumulation of the monies for this fund be by a five dollar assessment of each nonmilitary active member of the society, this assessment to be paid with the dues of the

society."

のはいかればか

We believe that the above resolutions represent one of the most sensible gestures made toward postwar planning that we have yet found. It frankly faces a situation that will almost assuredly arise with the termination of the war. Our members who have sacrificed not only the comforts and happiness of civilian life but have risked their lives and future security, will, on their return, encounter very difficult problems, including personal adjustment and economic adjustment. Meetings, speech-making, parades, flag-waving and the streams of confetti may have their places in bestowing recognition to home-coming veterans, but unfortunately they are generally considered out of all rightful proportion to their intrinsic value. Concrete aid in postwar adjustment is the only matter that should concern the intelligent; and doctors should be the first group to promulgate this principle.

It is our opinion that there is not a member of the society who, realizing the sound vision behind this action, will not approve with enthusiasm and with the conviction that he is doing his part in constructive postwar planning for his colleagues now in service.

### Broome County

The following committees of the county society have been appointed: economic committee: Dr. R. W. Rice, chairman, Dr. J. W. Colella, Dr. C. J. Marshall; legislative committee: Dr. G. C. Vogt, chairman, Dr. W. B. Aten, Dr. E. R. Dickson, Dr. C. R. Seymour; library committee: Dr. S. B. Blakely, chairman, Dr. H. W. Davis, Dr. W. H. Hobbs: membership committee: Dr. R. J. Mc. Blakely, chairman, Dr. H. W. Davis, Dr. W. H. Hobbs; membership committee: Dr. R. J. Mc-Mahon, chairman, Dr. J. A. Kalb; milk commission: Dr. P. H. Shaw, chairman, Dr. S. M. Allerton, Dr. H. B. Marvin, Dr. Mary J. Ross; public health committee: Dr. R. M. Vincent, chairman, Dr. W. J. Farrell, Dr. C. J. Longstreet, Dr. S. E. McManis, Dr. Vesta Rogers, Dr. A. J. Stillson; public relations committee: Dr. C. M. Allaben, chairman, Dr. E. R. Dickson, Dr. F. M. Dyer, Dr. E. M. Jones, Dr. G. C. Vogt, Dr. V. M. Maddi, Dr. R. W. Rice, and Dr. J. M. Touhey.

## Cayuga County

The list of officers of the county society is now omplete and is as follows: president—Dr. Harry S. Bull, of Auburn; vice-president—Dr. Clinton E. Goodwin, of Weedsport; secretary—Dr. L. W. Sincerbeaux, of Auburn; and treasurer—Dr. Leonard H. Rothschild, of Auburn; board of censors—Dr. Bernard L. Cullen, Dr. Walter B. Wilson, Dr. G. Perry Ross, Dr. William A. Tucker, and Dr. Jason L. Wiley: delerate to the State and Dr. Jason L. Wiley; delegate to the State

Convention-Dr. Harry Bull; alternate delegate-Dr. Alfred K. Bates; delegate to the seventh District Branch—Dr. A. K. Bates, and alternate delegate—Dr. Raymond F. Johnson.

The committees for the society for 1944 are: public health: Dr. John W. Copeland, chairman, Dr. George B. Adams, Dr. Norman L. Woodford; workmen's compensation: Dr. R. F. Johnson, chairman, Dr. W. B. Wilson, Dr. J. L. Wiley; grievance committee: Dr. B. L. Cullen, chairman, Dr. A. B. Chidester, Dr. H. I. Davenport, Dr. E. J. Kompton: advisory committee to Women's Dr. A. B. Chidester, Dr. H. I. Davenport, Dr. E. J. Kempton; advisory committee to Women's Auxiliary: Dr. Mary W. Kirkwood, chairman, Dr. Lillian A. Treat, Dr. Ila Moser; economics committee: Dr. Louis D. Burlington, chairman, Dr. A. K. Bates, Dr. W. A. Tucker, Dr. F. L. Holcomb; public relations: Dr. A. K. Bates, chairman, Dr. C. W. Bullard, Dr. L. H. Rothschild; cancer control: Dr. G. B. Adams, chairman, Dr. A. K. Bates, Dr. R. F. Johnson; school advisory: Dr. George C. Sincerbeaux, chairman, Dr. B. L. Cullen, Dr. Allan H. Kirkwood; war participation committee: Dr. Raymond F. Johnson, chairman, Dr. Milo L. Seccomb; advisory committee to Dunn and McCarthy: Dr. G. Perry Ross, chairman, Dr. Allan Kirkwood, Dr. W. B. Ross, chairman, Dr. Allan Kirkwood, Dr. W. B. Wilson; committee on service board: Dr. Cornelius F. McCarthy, chairman, Dr. R. F. Johnson, Dr. Leonard W. Sincerbeaux; legislative committee: Dr. C. F. McCarthy, chairman, Dr. A. Spadaro, Dr. F. L. DeFurio; and historian: Dr. G. F. McCarthy. C. F. McCarthy.

### Chautaugua County

Dr. Oscar T. Barber, of Fredonia, was elected president of the Chautauqua County Medical Society at its annual meeting held on December 16 in Jamestown.

Other officers chosen were: vice-president, Dr. M. J. Johnson, of Jamestown; secretary, Dr. Edgar Bieber, of Dunkirk; treasurer, Dr. Clive E. Hallenbeck, of Dunkirk.

A paper was delivered by Dr. Burton M. Shinners.

of Dunkirk.

The county society went on record as opposing the proposed national health insurance bill because it concentrates all practice of medicine and hospital administration in the hands of one person, the surgeon general.\*

#### Erie County

Dr. John D. Naples was elected president of the Medical Society of the County of Erie on December

Other officers elected are: first vice-president, Dr. A. H. Aaron; second vice-president, Dr. Porter A. Steele; secretary, Dr. Louise W. Beamis; treasurer, Dr. Ralph M. DeGraff; public health chairman, Dr. John W. Kohl; legislation chairman, Dr. Edmund A. Machey; economic chairman, Dr. Edmund A. Machey; economic chairman, Dr. Edward G. Winkler; membership chairman, Dr. Arthur F. Glaeser; delegates to the State Convention: Dr. Albert A. Gartner, Dr. Nelson W. Strohm, Dr. John T. Donovan, and Dr. Harold G. Brannie F. Francis F. F. Brown; and board of censors: Dr. Francis E. Fronczak, Dr. Eugene M. Sullivan, Dr. Charles W. Bethune, Dr. Francis J. Bullah, and Dr. Clyde L. Randall.

Dr. Harold Brown, the retiring president, outlined a system recently adopted by the society which has proved its greatest value during the in-

fluenza epidemic.

#### Medical News

#### Chace Reports on Studies of Future Medical Problems

R. ARTHUR F. Chace, president of the New York Academy of Medicine, said at the institution's annual meeting held on January 6 that the Academy was earnestly seeking to anticipate the form of society in which we shall live and was "in the process of adjusting medicine, in its broadest sense, to the new social order."

Studies on these problems, Dr. Chace reported, are being carried out by a special committee on medicine and the changing world order, consisting of fourteen leading physicians and thirty-five leaders of thought in labor, law, social work, nursing,

medical education, dentistry, and public health.
"Our first year of study," he said, "has convinced us that the social pattern of the immediate future will be influenced by planning on the part of the government, industry, labor, and consumers, and that the Academy can and must play an active part in the adjustment of medicine and public health to this new social order.

"An editorial committee, consisting of Dr. Iago Galdston, Mr. Lawrence Frank, and Prof. Bernhard J. Stern, has begun to prepare the committee's final report. This report we hope to have finished during 1944, and it is our expectation that it will offer fundamental data and concrete help toward the solution of the problems in medical service which we in medicine must thoughtfully and courageously face."

The committee on medical education of the Academy, Dr. Chace reported, "is formulating plans for postgraduate education of the wartime graduates in medicine as well as for the thousands." of other physicians who will have been out of civil practice for a number of years.

"The accelerated medical course now being given to thousands of medical students, the cutailment to nine months' duration of hospital internships, the restrictions placed upon residencies and other forms of postgraduate instruction and training, dictated by the demands of the war threaten to unloose upon the public, once the property of the p peace is established, a host of inadequately trained physicians."

In the present and immediate future, he added, the medical men of all the world, and particularly the twenty-one republics of Central and South America and the West Indies, must turn to America, and to a great extent to New York City, for leader-

ship in the medical sciences. In response to a request from a member of the State Grievance Committee, Dr. Chace reported that "a great deal of time has been given to the study of the present law concerning abortions, and suggestions have been made for legislative change which would close the various technical loopholes that have been made use of by those who perform criminal abortions."

#### President Gets Bill to Aid Relocation of Physicians

THE House of Representatives has acted favorably on a measure to pay the moving expenses of civilian physicians and dentists who agree to practice for not less than one year in a community in need of their services. The bill provides for the payment of moving expenses plus a monthly allowance of \$250 for three months.

A community requesting the services of a physician or dentist would be required to pay 25 per cent of the relocation allowance. The relocated physician or dentist must comply with the licensure laws of the state to which he removes.

The bill, which was previously accepted by the Senate, has now gone to the President.

#### County News

Albany County

Dr. Joseph Lawrence, of Albany, Executive Officer of the New York State Medical Society, spoke on "An Analysis of the Wagner-Murray-Dingell Bill" at the January meeting of the Delmar Progress Club in Albany.'

Bronx County

A regular meeting of the county society was held

on January 19. Following an executive session Dr. Nathan B. Van Etten spoke on "The Social Responsibility of the Doctor.'

#### When It's All Over-What?

The following resolutions were drawn up by the Medical Economics Committee, approved by the Comitia Minora, and presented at the October

\* Asterisk indicates that item is from a local newspaper.

meeting of the society with the direction that they be published in the Bulletin before being introduced They were for action at the December meeting. passed at the meeting held on January 19.

"WHEREAS: One-third of the membership of the Bronx County Medical Society has joined the armed forces of the United States; and

"WHEREAS: They have done this in the spirit of patriotism regardless of economic and social sacrifices; and

"WHEREAS: The Bronx County Medical Society in recognition of these patriotic duties and sacrifices desires to be in a position to aid these members toward re-establishing their private practice in the postwar period of readjustment; therefore be it

"Resolved: That the Bronx County Medical Society establish a fund to be known as the Postwar Emergency Loan Fund, this fund to be administered by the Loan Committee as set forth

In 1931 he returned to England and worked as clinical assistant in the Hospital for Sick Children, the Royal Chest Hospital, and the nose and throat department of St. Bartholomew's, before taking up full-time work in psychological medicine at the Maudsley Hospital.

Dr. George B. Dorff, Brooklyn specialist in glandular disturbances, has been re-elected president of the East New York Medical Society.

Dr. Dorff is in his second term as the society's president. He has charge of the children's endocrine clinic at Bellevue Hospital and is also associated with Beth-El Hospital, Brooklyn. Trustees of the society who were re-elected are Dr. Morris Ant, Dr. William Levine, and Dr. Hyman Teperson.

More than a third of the society's 400 members are now in uniform. Others are cooperating with Selective Service officials as examining physicians. A speakers' bureau is maintained in the East New York, Bedford, and Brownsville districts. The speakers accept invitations to talk before fraternal and civic groups on health problems.

The 598th regular meeting of the Society of Medical Jurisprudence was held at the New York

Academy of Medicine on January 10.

The program of the evening was as follows: address of the retiring president, "Remarks on the trend and the Progress of the Society's Activities, by Gustave J. Noback, M.A., Ph.D.; address of the incoming president, "I Wonder Why—The Mysteries of Science," by Gustavus T. Kirby. E.E., LL.B., M.P.E.; "Military Tropical Medicine," by Anthony Bassler, M.D., F.A.C.P., LL.D.; and a sound film in color on "Amebiasis," produced by the National Gastroenterological Association the National Gastroenterological Association.

A combined meeting of the Eastern Section of the American Trudeau Society and the Tuberculosis Sanatorium Conference of Metropolitan New York was held on Friday, January 21, at the Hotel Pennsylvania, in New York City.

Pennsylvania, in New York City.

Topics discussed at the morning session included:
Fluorescence Microscopy of the Tubercle Bacillus;
The Fate of Infants or Very Young Children with
Tuberculosis; and X-Ray Studies of Atypical
Pneumonia. During the afternoon session, the
subjects for discussion were: Coexisting Syphilis
and Tuberculosis in the Negro; Tuberculous
Bronchitis; and Indications and Risks Involved
in Pulmonary Beaution for Pulmonary Tuberin Pulmonary Resection for Pulmonary Tuber-The evening session at 7:30 P.M., was devoted to a symposium and panel discussion on

"Dust Inhalation Diseases of the Lungs."
Mr. David R. Lymn, Gaylord Farm Sanatorium, Wallingford, Conn., was the speaker at the luncheon rainingtord, Conn., was the speaker at the luncheon session. The speakers at the other sessions were: Dr. J. Burns Amberson, Visiting Physician-In-Charge, Chest Service, Bellevue Hospital; Dr. Leopold Brahdy, Physician-In-Charge of Occupational Diseases of Employees of the City of New York, and Dr. Andre F. Cournand, Assistant Professor of Medicine, Columbia University College of Physicians and Surgeons: Dr. Clarence F. Gralessor of Medicine, Columbia University College of Physicians and Surgeons; Dr. Clarence F. Graham, Herman Biggs Memorial Hospital, Ithaca N. Y.; Dr. Leonard Greenburg, Executive Director, Division of Industrial Hygiene, New York State Department of Health; Dr. Reuben Hoffman, Maryland Tuberculosis Sanatorium, Henrytown, Maryland; Dr. Foster Murray, Director of

Tuberculosis Service, Kingston Avenue Hospital, Brooklyn; Dr. Richard H. Overholt, Brookline, Massachusetts; Dr. H. McLeod Riggins, Medical Director, Triboro Hospital; Dr. E. C. Showacre, Cornell University, Ithaca; and Dr. Henry S. Willis, William H. Maybury Sanatorium, North-ville, Michigan.

#### Herkimer County

At a meeting of the county society held in Herkimer on December 14, 1943, officers were elected as mer on December 14, 1943, officers were elected as follows: president, Dr. Dominick F. Aloisio, Little Falls; first vice-president, Dr. F. M. Neuendorf, Mohawk; second vice-president, Dr. B. J. Kelly, Frankfort; third vice-president, Dr. Charles Lanning, Herkimer; librarian, Dr. G. S. Eveleth, Little Falls; secretary, Dr. Fred C. Sabin, Little Falls; treasurer, Dr. Albert L. Fagan, Herkimer; board of censors: Dr. F. H. Moore, Dr. Sabin, Dr. Harold Buckbee, Dr. H. J. Sheffield, and Dr. C. C. Whittemore

Dr. Aloisio was named delegate to the State Medical Society meeting to be held in New York in May, and Dr. Neuendorf, was chosen first alter-

nate delegate.

The executive committee named by Dr. Aloisio is headed by Dr. B. G. Shults, the retiring president. Other members are Dr. F. H. Moore, Dr. L. P. Jones, Dr. George J. Frank, Dr. Sabin, and Dr. A. B. Santry.

Dr. George S. Eveleth, Little Falls, one of the oldest practicing physicians in Herkimer County, read a paper at the meeting. His topic was "Medi-

cine in Retrospect Over Fifty-five Years."

Hans A. W. Kotrnetz, M.D., and his wife,
Margarete E. Kotrnetz, M.D., have made Herkimer their home and their application to transfer their membership from Otsego County to Herkimer County Society was approved. These physicians have recently been granted their citizenship and, at their request, have been listed as available for military service with the Procurement and Assignment Service.—FRED C. SABIN, M.D., Secretary.

#### Lewis County

The following officers for the county society have been elected for the year 1944: president—Dr. David J. O'Connor, of Croghan; vice-president Dr. Edgar O. Boggs, of Lowville; and secretary-treasurer—Dr. Harry E. Chapin, of Lowville. The censors are: Dr. Bruce M. Phelps, Dr. H. E. Chapin, and Dr. Gregori O. Volovic, all of Lowville. The delegate to the State Society is Dr. Thomas A. Lynch, of Lowville. The committee on Legislation consists of Dr. D. J. O'Connor, Dr. B. M. Phelps, and Dr. H. E. Chapin. Members of the committee on Public Health are Dr. Thomas Lynch, Dr. D. J. O'Connor, and Dr. Rudmin. Other committees are: the subcommittee on industrial health: Dr. D. J. O'Connor and Dr. H. E. Chapin; committee on school health: Dr. B. M. Phelps and Dr. Thomas Lynch; subcommittee on tuberculosis: Dr. B. M. Phelps.

#### Livingston County

Members of the Livingston County Medical Society met for their annual meeting at the Big Tree Inn, Geneseo, Monday evening, December 20 for dinner.

Dr. Earle B. Mahoney, assistant professor of surgery at the University of Rochester, addressed the members on the topic of "The Treatment of

A list of physicians who have signified their willingness to accept new patients and a list of doctors who will make night calls on these patients have been compiled by the economic and public relations committees. Anyone desiring to obtain the names of doctors in his neighborhood who are available for such calls may contact the medical society office during the day or the Nurses Official Registry at night.\*

At a stated meeting of the Buffalo Academy of Medicine, held in January 12 at the Hotel Statler, Dr. Philip Levine, of New York City, spoke on "The Clinical Importance of Isoimmunization by the Rh Factor."

Discussion of the paper was given by Dr. Douglas P. Arnold, of Buffalo, Dr. William J. Orr, of Buffalo,

and Dr. Louis A. Siegel.

Dr. Levine has done much experimental research on the Rh factor, particularly in connection with fetal erythroblastosis, and the practical application of his findings has been of significance in determining the pathogenesis of this disease.

The next meeting of the Academy will be held

Wednesday, February 9.

Appointment of Dr. Grant L. Rasmussen as associate professor of anatomy in the School of Medicine of the University of Buffalo has been announced by Chancellor Samuel P. Capen.

Dr. Rasmussen, graduate of the University of Minnesota, has been on the faculty of the University of South Carolina Medical School since 1934 and has been assistant professor of anatomy there since 1940.

Dr. Harvey P. Hoffman, Buffalo physician, was appointed lecturer in medical economics. Hoffman, who received his medical degree in 1914 from the University of Illinois, is a past-president

of the Eric County Medical Society.

Fifty-eight men and women received medical degrees from the University of Buffalo at its special medical commencement on December 29. The commencement at which Dr. James E. King, physician and gynecologist, gave an address entitled "Medicine Looks Ahead," was the ninety-eighth for the School of Medicine.

The exercises were the first since Army and Navy training units were established at the school. Of the graduates, 46 were commissioned first lieutenants in the Army Medical Officers Reserve Corps and 6 were commissioned lieutenants (junior grade) in the Naval Reserve. They will remain on inactive status until they complete their internation.\*

ships.

Franklin County

Major Bruno S. Harwood, former nose and throat specialist in Saranac Lake, who has been with the armed forces at Camp Sutton, S.C., has returned to Saranac Lake after having received a discharge from the Army after three years' service. He is planning to resume practice.\*

Fulton County

The following is a list of physicians who are officers of the county society for 1944: presidentMorris Kennedy, vice-president—John F. Samo, secretary—Louis Tremante, and treasurer—Avery H. Sarno; board of censors-Matthias F. Donnelly, chairman, Frank G. Calder, and Walter R Grunewald; delegate to the State Convention-S. C. Clemans; alternate delegate to the State Convention—Arthur R. Wilsey.

The following doctors have been appointed to committees by Dr. Kennedy for the year 1941: public health—R. L. Ellithorpe, W. R. Grunewald. B. E. Chapman; compensation—H. B. Riggs, Claude Bledsoe, B. A. Winne; program—D. Battaglia, W. F. Hesek, J. F. Sarno, Claude Bledsoe, S. L. Russell, A. Goodwin; economics-A. H Sarno; medical service and public relations—B G. McKillip, H. H. Oaksford, V. R. Ehle, S. C. Clemans, M. F. Donnelly; legislative—S. C. Clemans, S. J. Colton, F. G. Calder; Woman's Auxilian,—E. N. Perkins, B. G. McKillip, V. R. Ehle, cancer—W. J. Kennedy, E. G. Gilmore, H. C. Denham; entertainment, H. H. Oaksford, M. F. Donnelly, J. Shannon, K. Durand; war participation—H. C. Denham, L. Tremante, A. H. Sarno.

#### Genesee County

Dr. I. A. Cole, of Batavia, is the new president of the Genesee County Medical Society, succeeding

Dr. Ward B. Manchester, of Batavia.

Dr. Paul P. Welsh, of Le Roy, has been named vice-president in Dr. Cole's place and Dr. Peter J. Di Natale, of Batavia, was again chosen secretary and trensurer. Dr. Di Natale was named delegate to the New York State Medical Society for the next two years with Dr. C. C. Koostones elternate. next two years, with Dr. C. C. Koester as alternate.

#### Greater New York

New Yorkers had their first opportunity to hear an authoritative account of the treatment of nar neurosis in Britain on January 3, when Dr. Walter S. Maclay, noted British psychiatrist, addressed an open meeting jointly sponsored by the Kings County Medical Society, the Brooklyn Chapter of the American Red Cross, and the Brooklyn Council for Sociel Planning, Mortimer Brenner. Council for Social Planning. Mortimer Brennet, chairman of the Brooklyn Council for Social Plan-

Dr. Maclay, now in the United States on the invitation of the American Psychiatric Association, ning, presided. is medical superintendent of the Mill Hill Emergency Hospital in London. This hospital, built originally for air raid casualties, is now devoted

entirely to the treatment of neurosis.

Dr. Maclay's lecture was illustrated by the showing of a technical film which portrays the organization and working of the Emergency Medical Service neurosis center. His talk covered the effect of bombing on the civilian population and on children, the effects of evacuation on children, and other problems created by war developments.

Dr. Maclay holds appointments as physician in psychological medicine to the West London Hospital and to the King George Hospital at Illord He was physician to the outpatient department of Maudsley Hospital, which was closed at the outpreak of war, half of its staff forming the nucleus of the staff of Mill Hill.

Born in 1901, son of the first Baron Maclay, Dr. Maclay was educated at Fettes College, Edinburgh, St. John's College, Cambridge, and at St. Bartholomew's Hospital, London. He then worked as house physician and house surgeon in Glasgow for one year, and spent three years in native hospitals in East, South, and Central Africa.

In 1931 he returned to England and worked as clinical assistant in the Hospital for Sick Children, the Royal Chest Hospital, and the nose and throat department of St. Bartholomew's, before taking up full-time work in psychological medicine at the Maudsley Hospital.

Dr. George B. Dorff, Brooklyn specialist in glandular disturbances, has been re-elected president of the East New York Medical Society.

Dr. Dorff is in his second term as the society's president. He has charge of the children's endocrine clinic at Bellevue Hospital and is also associated with Beth-El Hospital, Brooklyn. Trustees of the society who were re-elected are Dr. Morris Ant, Dr. William Levine, and Dr. Hyman Teperson.

More than a third of the society's 400 members are now in uniform. Others are cooperating with Selective Service officials as examining physicians. A speakers' bureau is maintained in the East New York, Bedford, and Brownsville districts. The speakers accept invitations to talk before fraternal and civic groups on health problems.

The 598th regular meeting of the Society of Medical Jurisprudence was held at the New York

Academy of Medicine on January 10.

The program of the evening was as follows: address of the retiring president, "Remarks on the trend and the Progress of the Society's Activities,' by Gustave J. Noback, M.A., Ph.D.; address of the incoming president, "I Wonder Why—The Mysteries of Science," by Gustavus T. Kirby, E.E., LL.B., M.P.E.; "Military Tropical Medicine," by Anthony Bassler, M.D., F.A.C.P., LL.D.; and a sound film in color on "Amebiasis," produced by the National Gastroepterological Association the National Gastroenterological Association.

A combined meeting of the Eastern Section of the American Trudeau Society and the Tuberculosis Sanatorium Conference of Metropolitan New York was held on Friday, January 21, at the Hotel Pennsylvania, in New York City.

Topics discussed at the morning session included: Fluorescence Microscopy of the Tubercle Bacillus; The Fate of Infants or Very Young Children with Tuberculosis; and X-Ray Studies of Atypical Pneumonia. During the afternoon session, the subjects for discussion pages. Convicting Symbilis subjects for discussion were: Coexisting Syphilis and Tuberculosis in the Negro; Tuberculous Bronchitis; and Indications and Risks Involved in Pulmonary Resection for Pulmonary Tuber-culosis. The evening session at 7:30 p.m., was devoted to a symposium and panel discussion on "Dust Inhalation Diseases of the Lungs."

Mr. David R. Lymn, Gaylord Farm Sanatorium, Wallingford, Conn., was the speaker at the luncheon Dr. J. Burns Amberson, Visiting Physician-In-Charge, Chest Service, Bellevue Hospital; Dr. Leopold Brahdy, Physician-In-Charge of Occupational Diseases of Employees of the City of New York, and Dr. Andre F. Cournand, Assistant Professor of Medicine. Columbia University College fessor of Medicine, Columbia University College lessor of Medicine, Columbia University College of Physicians and Surgeons; Dr. Clarence F. Graham, Herman Biggs Memorial Hospital, Ithaca N. Y.; Dr. Leonard Greenburg, Executive Director, Division of Industrial Hygiene, New York State Department of Health: Dr. Reuben Hoffman, Maryland Tuberculosis Sanatorium, Henrytown, Maryland; Dr. Foster Murray, Director of

Aubertonosis Service, Mingston Avenue Hospital, Brooklyn; Dr. Richard H. Overholt, Brookline, Massachusetts; Dr. H. McLeod Riggins, Medical Director, Triboro Hospital; Dr. E. C. Showacre, Cornell University, Ithaca; and Dr. Henry S. Willis, William H. Maybury Sanatorium, Northville, Michigan. Tuberculosis Service, Kingston Avenue Hospital,

#### Herkimer County

At a meeting of the county society held in Herkimer on December 14, 1943, officers were elected as follows: president, Dr. Dominick F. Aloisio, Little Falls; first vice-president, Dr. F. M. Neuendorf, Mohawk; second vice-president, Dr. B. J. Kelly, Frankfort; third vice-president, Dr. Charles Lanning, Herkimer; librarian, Dr. G. S. Eveleth, Little Falls; secretary, Dr. Fred C. Sahin Little Falls; Falls; secretary, Dr. Fred C. Sabin, Little Falls; treasurer, Dr. Albert L. Fagan, Herkimer; board of censors: Dr. F. H. Moore, Dr. Sabin, Dr. Harold Buckbee, Dr. H. J. Sheffield, and Dr. C. C. Whitte-

Dr. Aloisio was named delegate to the State Medical Society meeting to be held in New York in May, and Dr. Neuendorf, was chosen first alter-

nate delegate.

The executive committee named by Dr. Aloisio is headed by Dr. B. G. Shults, the retiring president. Other members are Dr. F. H. Moore, Dr. L. P. Jones, Dr. George J. Frank, Dr. Sabin, and Dr. A. B. Santry.

Dr. George S. Eveleth, Little Falls, one of the oldest practicing physicians in Herkimer County, read a paper at the meeting. His topic was "Medicine in Retrospect Over Fifty-five Years."

Hans A. W. Kotrnetz, M.D., and his wife, Margarete E. Kotrnetz, M.D., have made Herkimer their home and their application to transfer their membership from Otsego County to Herkimer County Society was approved. These physicians have recently been granted their citizenship and, at their request, have been listed as available for military service with the Procurement and Assignment Service.—Fred C. Sabin, M.D., Secretary.

#### Lewis County

The following officers for the county society have been elected for the year 1944: president—Dr. David J. O'Connor, of Croghan; vice-president Dr. David 3. O Collind, of Crognan, Vice-president —Dr. Edgar O. Boggs, of Lowville; and secretary-treasurer—Dr. Harry E. Chapin, of Lowville. The censors are: Dr. Bruce M. Phelps, Dr. H. E. Chapin, and Dr. Gregori O. Volovic, all of Lowville. The delegate to the State Society is Dr. E. O. Boggs, and the alternate delegate is Dr. Thomas A. Lynch of Lowville. The committee Thomas A. Lynch, of Lowville. The committee on Legislation consists of Dr. D. J. O'Connor, Dr. B. M. Phelps, and Dr. H. E. Chapin. Members of the committee on Public Health are Dr. Thomas Lynch, Dr. D. J. O'Connor, and Dr. Rudmin. Other committees are: the subcommittee on industrial health: Dr. D. J. O'Connor and Dr. H. E. Chapin; committee on school health: Dr. B. M. Phelps and Dr. Thomas Lynch; subcommittee on tuberculosis: Dr. B. M. Phelps.

#### Livingston County

Members of the Livingston County Medical Society met for their annual meeting at the Big Tree Inn, Geneseo, Monday evening, December 20 for dinner

Dr. Earle B. Mahoney, assistant professor of surgery at the University of Rochester, addressed the members on the topic of "The Treatment of

Burns and Experiences at the Cocoanut Grove Disaster."

Dr. Glenn J. Doolittle, of Sonyea, was re-elected president of the society; Dr. Howard Schneckenburger, of Nunda, vice-president; Dr. Foster Hamilton, of Hemlock, secretary and treasurer.

#### Monroe County

Lt. Comdr. Richard A. Cupaiuoli, (MC), USNR Sampson, spoke on December 21 at the one hundred and twenty-third annual meeting of the Medical Society of the County of Monroe. His subject was "Problems of Medical Officers of the Navy in Amphibious Operations." Other speakers included Miss Veronica Maher, executive director, American Red Cross; Alvah G. Strong, Food Panel, OPA; and officers of the Medical Society of the State of Committee chairmen presented their New York. annual reports. Dinner at the Rochester Academy of Medicine at 6:30 P.M. was followed by the program at 8:30 P.M.

On December 21 two Rochester physicians watched the christening of a Liberty Ship named for their late friend, Sir Frederick Banting, of Toronto, Canada, who collaborated in the discovery of insulin.

They were Dr. John R. Williams, chairman of the ship's sponsoring committee, and Dr. George H. Whipple, who joined other prominent medical men from all parts of the United States and Canada at the launching exercises at the Bethlehem-Fairchild shipyard in Baltimore.

Lady Banting, widow of the Canadian doctor who was killed in an airplane accident over New-foundland in 1941, christened the vessel. She is a fifth-year medical student at the University of Toronto, where her husband conducted his research, and a member of the Canadian Women's Corps.

Guests included Leighton G. McCarthy, Canadian ambassador to the United States; Dr. Philip Bard, president of the American Physiological Society; Dr. Ian Urquhart of the University of Toronto, and other leaders in education, medical, and diplomatic circles.\*

Montgomery County

The following is the list of officers elected at the annual meeting of the Medical Society of the County of Montgomery; these were elected on Dec. 14, 1943, and to serve for the year 1944: president—Dr. C. Armstrong Spence, of Amsterdam; vice-president—Dr. James A. Dickson, of Amsterdam; treasurer—Dr. Melvin T. Woodhead of Amsterdam; and secretary-Dr. Stella Partyka, of Amsterdam.

The delegate to the Medical Society of the State of New York is Dr. Robert C. Simpson, of Amsterdam, and the alternate delegate is Dr. Patrick J. Fitzgibbons of Amsterdam. The delegate to the Fourth District Branch is Dr. P. J. Fitzgibbons.

Nassau County

J. Louis Neff, of Garden City, veteran executive secretary of the Nassau Medical Society, who retired on December 31 to become executive director of the American Society for the Control of Cancer, was feted at the annual dinner of the medical society in the Wheatley Hills Golf Club on December 15.

The affair was a surprise to Mr. Neff, who had

expected the usual entertainment and speaking which has been traditional with society members.

One of the largest turnouts of members in recent years appeared to pay their respects to Mr. Nefi. He was presented with several pieces of matched luggage by the society officers and the Nassau County Cancer Committee, in addition to a check by society members.

Presentations were made by Dr. Arthur. C. Martin, past-president, for the past-presidents and members, and by Dr. Eugene Coon for the

cancer committee board.

Mr. Neff has been secretary of the society for nearly twenty years, and secretary of the Cancer Committee since it was organized. Mrs. Martha T. Ackerson, a member of the society's office staff, will take over Mr. Neff's duties as business manager for the society.\*

#### New York County

The following New York physicians are officers of the newly formed American Academy of Allergy: Robert Chobot, president; Will C. Spain, secretary; Robert A. Cooke, executive committeeman.

Dr. Walter B. Cannon, physiologist, for forty-five years associated with Harvard University, has joined the faculty of the New York University College of Medicine as a visiting professor, it was announced recently.

Mrs. Albert D. Lasker, of New York City, and Dr. George H. Preston, of Baltimore, State Commissioner of Mental Hygiene in Maryland and president of the American Orthopsychiatric Association, have been elected to the board of directors of the National Committee for Mental Hygiene, 1790 Broadway, it was announced by Orlando B. Willcox, chairman of the board.

Niagara County

Dr. Grant Guillemont was elected president of the county society at the annual organization meet-

of the society.

Others elected at the meeting were Dr. William Mathews, vice-president; Dr. Charles M. Brent, secretary, and Dr. George Stoll, treasurer.

Named to the board of censors of the society are Drs. Roy Wixson, of Niagara Falls, R. R. B. Fitzgerald, of Lockport, and Robert Reagan, of

North Tonawanda. Committee chairmen include Dr. Reagan, legislation; Dr. Joseph P. LaDuca, education and public health; Dr. William Peart, Sanborn, economics and medical education; Dr. H. U. Cramer, compensation, and Dr. Harry C. Dumville, war prepared

paredness. Dr. Guy S. Philbrick and Dr. Peart were named delegates to the annual convention of the New York State Medical Society.\*

Oneida County

Dr. A. DeWitt Brown, former Albany surgeon,

has opened an office in New Hartford. He is a graduate of Union College and Albany Medical College. He served his internship at the Albany Hospital and for six months was resident physician in anesthesia there. Until recently he was associated with Dr. Frank C. Maxon, Jr., Coeymans, as assistant.

Dr. Brown is a member of the American Society of Anesthetists and a diplomat of the National

Board of Medical Examiners.

Mrs. Brown, formerly Dr. Esther Moeller, also a graduate of Albany Medical College and a diplomat of the National Board of Medical Examiners, served her internship at the Memorial Hospital, Albany. At present she is serving an assistant residency in pathology at the Albany Hospital and will be there until July 1. After that date she will join her husband in the practice of medicine in New Hartford.\*

#### Onondaga County

A joint meeting of the county society and the Syracuse Academy of Medicine was held in the University Club in Syracuse on January 4.

The program featured an address by the retiring president of the Academy, Dr. J. G. Fred Hiss, and "Meningitis in Syracuse During 1943," by Dr. A. Clement Silverman, with the discussion opened by Dr. O. W. H. Mitchell.

#### Putnam County

Drs. Charles L. Fox, Jr., and Camille K. Cayley participated in a symposium on "Progress in Chemotherapy" held by the Putnam County Medical Society at Carmel, New York, on January 5.

#### Richmond County

Dr. Edward D. Wisely, of St. George, Staten Island. has left for Marietta, Georgia, to join the medical staff of the Bell Aircraft Corporation. He will be one of the examining physicians.

In accepting the position with the Bell Corporation, Dr. Wisely suspends a practice that has continued for more than forty-five years. He is said to be one of the oldest practicing physicians on the Island, of which he is a native.

He is also one of the oldest members of the Richmond County Medical Society, which for twenty-five years he served as secretary and treasurer.

For more than twenty years he was connected with the City Health Department, holding the office of deputy commissioner in charge of Richmond Borough. He retired in 1917.

Chosen president of the Alumni Association of the Class of 1896 of the College of Physicians and Surgeons of Columbia University many years ago,

he still holds this office.

"For a long time I have been trying to get into war work and at last the opportunity has presented itself," he said. "I'll be able to do my bit for my country through the Bell Corporation."\*

#### Saratoga County

The Saratoga County Medical Society re-elected the following officers at its annual meeting held October 14, 1943: president, Dr. Mark D. Duby, Schuylerville; vice-president, Dr. Frederick G. Eaton, Saratoga Springs; secretary, Dr. Malcolm J. Magovern, Saratoga Springs; treasurer, Dr. W. John Maby, Mechanicville. The delegate to the State Society is Dr. G. Scott Towne, of Saratoga Springs; the alternate is Dr. John R. MacElroy, of Jonesville.

#### Schenectady County

The following officers have been elected by the Schenectady County Medical Society for the year 1944: president, Dr. Charles F. Rourke; vice-president, Dr. Glen Smith; secretary, Dr. Nelson H. Rust; treasurer, Dr. Alfred Grussner; delegate to the State Society, Dr. Joseph H. Cornell; alter-

nate, Dr. Harry Reynolds; board of censors: Dr. William Fodder, Dr. Harry Reynolds, Dr. James York; delegate to the Fourth District Branch, Dr. B. L. Vosburgh; alternate, Dr. James Blake.

Standing committees of the county society for 1944 are: hearing committee, Dr. Edward B. O'Keefe, chairman; personal property committee, Dr. William J. Jameson, chairman; research committee, Dr. William E. Gaseley, chairman; ophthalmia committee, Dr. William C. Ostrom, chairman; sick committee, Dr. Ralph D. Reid, chairman; photographic committee, Dr. Ellis Kellert, chairman; photographic committee, Dr. Charles W. Woodall, chairman; medical advisory committee to the County Welfare Unit, Dr. Charles F. Rourke; program committee, Dr. James M. Blake, chairman; public health committee, Dr. John H. Collins, chairman; public relations committee, Dr. Gomer Richards, chairman; library committee, Dr. Judson B. Gilbert, chairman; war participation committee, Dr. Frank L. Sullivan, chairman; medical relief committee for doctors in service, Dr. William L. Fodder, chairman; entertainment committee, Dr. D. Glen Smith, chairman; medical economics committee, Dr. Beverly L. Vosburgh, chairman; advisory committee to Woman's Auxilliary, Dr. Joseph H. Cornell, chairman; maternal welfare committee, Dr. William M. Mallia, chairman; gasoline grievance committee, Dr. Charles E. Wiedenman, chairman; compensation committee, elective.

The regular monthly meeting of the county society was held in the Ellis Hospital Library on January 11 at 8:30 P.M.

The speaker was Dr. Lawrence A. Kohn, associate professor of medicine at the University of Rochester and attending physician at Strong Memorial Hospital in that city. His subject was "Clinical Aspects of Atypical Pneumonia."

The discussions were by Dr. Garrett Clowe and

Dr. Harry Reynolds.

#### Sullivan County

The following is the list of officers of the county society for 1944: president, Dr. R. S. Breakey, Monticello; vice-president, Dr. Nathan Nemerson, Monticello; secretary and treasurer, Dr. Deming S. Payne, Liberty; board of censors: Dr. Jacob Kornblum, Monticello; Dr. Morris A. Cohn, Monticello; Dr. Cornelius Duggan, Bethel; Dr. Luther F. Grant, Liberty; Dr. William Fernhoff, Woodridge; Workmen's Compensation Committee, Dr. Harry Golembe and Dr. George Seiken, and alternates, Dr. Louis Launer, and Dr. Alfred Hesse; delegates to the State Convention, Dr. B. Abramowitz, Monticello; alternate, Dr. L. F. Grant, Liberty.

#### Washington County

The officers of the county society for the year 1944 are as follows: president, Dr. Roy E. Borrowman, Fort Edward; vice-president, Dr. Zenas V. D. Orton, Salem; secretary, Dr. Denver M. Vickers, Cambridge; treasurer, Dr. Charles A. Prescott, Hudson Falls; delegate to the State Convention, Dr. Denver M. Vickers; board of censors: Drs. Charles H. Holmes, Walter S. Bennett, and John L. Byrnes; committee on farm security administration: Drs. Byron C. Tillotson, Irwin V. Decker, and Dougald F. Macarthur; committee on legislation, Dr. Walter A. Leonard, chairman; com-

mittee on public relations, Dr. Michael A. Rogers, chairman; war participation committee, Drs. Edward V. Farrell, R. E. Borrowman, and Samuel Pashley, Jr.

#### Westchester County

A regular meeting of the county society was held

on January 18 at 8:30 r.m. at the Westchester Division of the New York Hospital, in White Plains.

"Public Health in Wartime" was the title of an address given by Dr. Edward S. Rogers, of Albany, Assistant Commissioner of the New York State Department of Health.

#### BRITISH AND AMERICAN MEDICINE YESTERDAY

A writer in the Edinburgh Review in 1820 concluded an article on American medical statistics with a series of rhetorical questions: "In the four quarters of the globe, who reads an American book? or goes to an American play? or looks at an American picture or statue? What does the world yet owe to American Physicians or Surgeons?"

These questions reflected the European attitude toward the United States not merely during the beginning of the last century but well into this,

To these slights Nathaniel Chapman answered in a characteristically American manner. In that same year he brought out a journal which was the precursor of the present American Journal of the Medical Sciences, and the title-page of the journal carried as its motto the quotation from the Edinburgh Review. No love was lost between the two English-speaking branches of medicine. Chapman, in 1824, pointed out the "impertinence and presumption" of English critics. He claimed that a particular technic for the treatment of stricture of the urethra, said to have been first described by an English surgeon, was in fact described by an American the year before. Contemporary English medical literature provided Chapman with full opportunities for questioning English gentility. Thomas Wakley, founder of the Lancet, used choice descriptions such as "bats," "owls," "cocksparrows," and "ninny-hammers" for prominent British practitioners, and these appellations were

matter that American critics were unlikely to

Minor events, such as the exploits of John St. John Long, a brilliant charlatan who imposed on pre-Victorian society, were further grist to the American mill. Streaks of sanity did, however, occasionally break through on both sides. Wakley, in 1831, could praise the American Journal of the Medical Sciences as being "in most respects superior to the great majority of European works of the same description"; and an American editor in 1846 could make the common-sense observation, "Where is the American who would not be pleased, nay gratified, to see his works republished, with or without annotations, in Great Britain?" None the less, the dreary game of fault-finding went on throughout the century, charges of ignorance and incompetence being apparently one of the main items of trade between the two countries.

One of the earliest signs that this unedifying futility was subsiding was a comment in the British Medical Journal in 1883. "Medical journalism in America shows great activity," it says, and speaks approvingly of a series of American publica-

In retrospect the Anglo-American hostility, as reflected in medical literature, had little to justify itself, and the conflict has ceased to have any meaning to the present generation, for the conditions from which it arose have long ago disappeared.—Bril. M.J.

#### Hospital News

#### Improvements

St. Elizabeth Hospital has purchased in Utica a tract of land which adjoins the hospital grounds and is nearly 100 feet wide and 665 feet in depth. It was the only remaining vacant land adjoining the hospital grounds and by its acquisition the hospital has completed its site so that it now owns approximately eighteen acres.\*

2

The construction of twenty-seven new buildings, now in progress, on a twenty-five-acre tract adjoining the present site of the Staten Island Area Hospital at New Dorp Beach, will more than double the capacity of that institution, according to an announcement by the Second Service Command.

announcement by the Second Service Command.

The new Army hospital occupies buildings formerly occupied by Seaside Hospital, which were built in 1887 on grounds acquired eight years before by St. John's Guild, a charitable organization. In 1940 the hospital entered an agreement with the New York Society for Relief of the Ruptured and Crippled under which the society operated the institution for children convalescing from orthopaedic disorders.

The War Department took over the institution in October, 1942, re-equipped it completely, and began a series of extensive alterations, among which were new plumbing and electrical systems, painting, and the enclosure of porches. Barracks and officers' quarters were built for the hospital personnel. The hospital began admitting soldier-patients from the metropolitan area two months ago.

Col. Ralph L. Cudlipp, Medical Corps, Regular Army, is commanding officer, in charge of the hospital's detachment of officers, nurses, and en-

The twenty-seven new buildings are expected to be completed in January. These include barracks, offices, warehouses, an orthopaedic shop, laboratories, day rooms, and a motor pool as well as hospital wards. In order to build these structures, the twenty-five-acre tract first had to be cleared. Among the buildings that were razed to make way for the new hospital was Mandia's Hotel, formerly

known as the George Munger Hotel.

The new hospital gives full medical service, including acute medicine, surgery, x-ray, laboratory. complete dental service, and all other advanced hospital procedures. Its location on the sandy, wind-swept Lower Bay is reported ideal for convalescence.\*

The Lincoln League of Watertown has presented the Mercy Hospital of that city with modern equipment greatly needed by the hospital for the treatment of certain types of heart trouble and many times employed in the treatment of some respiratory diseases and of infantile paralysis.

The equipment selected included a new type of oxygen tent and control apparatus known as the senior oxygenaire controls, tank cart, and removable ice container. This equipment operates without an electric motor and the danger from electrical sparks are thus done away with. In connection with it is also a government-approved analyzer. An oxygen cylinder truck and a carrier truck for the safe and silent transport of cylinder tanks to any part of the hospital were also purchased.

Sister Mary John, the superintendent of the hospital, acknowledged the gift with a letter of appre-

ciation and thanks.\*

A contract to purchase the former Tietz Music Store property has been negotiated by Memorial Hospital in Albany.

The hospital owns properties on either side of this property, which are used for nurses' quarters.

It is likely the third building will be put to the same use.\*

It was recently announced that St. Jerome Hospital in Batavia will engage in a building program costing \$500,000 instead of the \$250,000 project promised in the current building fund campaign, the project to await the availability of materials.\*

#### At the Helm

Dr. Nathan Ginsberg, of Long Beach, has been appointed to the clinical staff of Mount Sinai Hospital in New York City. His appointment is in the heart department. The doctor has practiced in Long Beach for the past eighteen years and is on the staff of the Long Beach Hospital as an associate physician.

Miss Dorothy V. Elliott, R.N., M.S., is the new directress of nurses at the North Country Community Hospital in Glen Cove. She received her Bache-

Asterisk indicates that item is from local newspaper.

lor of Science degree at Ohio State University, Columbus, Ohio, in 1937; she is a graduate of the Grace Hospital, Detroit, Michigan, and did postgraduate work at the Woman's Hospital, New York City

Before going to Glen Cove, Miss Elliott was science instructor at Glenville Hospital, Cleveland, Ohio, and later directress of nurses at the same hospital. For the past several years she has been educational director at the Grace Hospital, Detroit, Michigan. She received her Master's degree at Ohio State University in September of this year.

Miss Elliott is a member of the American Nurses'

Association, National League of Nursing Education, and the American Red Cross Nursing Service.\*

Louis H. Putnam, well-known hospital executive, has been appointed general manager of the House of St. Giles the Cripple in Brooklyn. In this capacity, he will be in direct charge of St. Giles' Hospital at 1346 President Street and the Convalescent Home in Garden City, Long Island.

For almost forty years, Mr. Putnam has been engaged in hospital management and social and child welfare activities. He is best known to residents of metropolitan New York for his work as superintendent of the Staten Island Hospital from 1929 to

1941.

Before coming to Staten Island, he had organized the West Virginia Society for Care, Cure, and Training of Crippled Children, and served as superintendent of the North Carolina Children's Board, the Florida State Industrial School, and the Mo-

while Country (Alabama) Juvenile Court System.

While in West Virginia, Mr. Putnam also was director of the State Board of Children's Guardians, vice-chairman of the West Virginia Liberty Loan Committee, and confidential agent under Governor

John J. Cornwell during World War I.

He is a member of the American Hospital Association and a former member of the Brooklyn Hospital Council.\*

Dr. Leverett D. Bristol, New York, health director of the American Telephone and Telegraph Company since 1929, has been appointed executive director of the Hospital Council of Greater New York, as of December 1. The council is a community planning agency to coordinate and improve the hospital and health services of New York City and to plan the economic development of these services in relation to community needs. It is made up of about twenty leading voluntary and government health, hospital, medical, welfare, and business organizations of the state and city and its work is carried on through a planning committee made up of representatives of member agencies. The council has a close working relationship with the United Hospital Fund of New York City. One of its immediate mediate projects will be to develop and plan for the present and postwar periods for the organized care of the sick in greater New York. Dr. Bristol's offices will be at 370 Lexington Avenue, New York 17.

Ralph E. Jones was re-elected president of the Board of Directors of Highland Hospital in Beacon at the annual meeting held on December 4. All

officers were renamed.

Herbert F. Haley was re-elected vice-president, Mrs. Simon Cahn, corresponding secretary, Mrs. Leonard J. Supple, recording secretary, Frederick W. Heaney, treasurer, and Hazel M. Crum, assistant treasurer.

This will be the third year Mr. Jones has served as president and Mr. Haley as vice-president.\*

Announcement of the appointment of Dr. Edward A. Klauber, of Stapleton, as attending physician, Dr. E. F. Fieramosca, of West Brighton, as adjunct attending physician, and Dr. E. Morris Gould, of Manhattan, as neuropsychiatric consul tant on the medical staff of Staten Island Hospital, has been made by William E. P. Collins, hospital superintendent.

Dr. Klauber is a general practitioner. He was graduated from Long Island College in 1924 and is

experienced in traumatic surgery.

Formerly clinical assistant, Dr. Fieramosca is an alumnus of Curtis High School, St. John's University, and Loyola University Medical School. He served his internship at St. James Hospital in Newark, New Jersey, and is a member of the Richmond County Medical Society and the American Medical Association.

Dr. Gould replaces Dr. Samuel Reback, neuropsychiatrist on the consultant and outpatient department staffs. The latter has been given a leave of absence for the duration to enter the U.S. Army

Dr. Gould is a Yale graduate and is a member of the American Board of Psychiatry and Neurology a director of neurology at Queens General Hospital on Long Island; consultant neurologist at Rock-away Beach (L.I.) Hospital, and St. John's Long Island College Hospital's department of neurology.

Mrs. Edna J. Griffin, a native of Nova Scotia and a graduate of Montreal General Hospital School of Nursing, has been engaged as superintendent of Goshen Hospital.

Mrs. Griffin was assistant director of nurses in Wyckoff Heights Hospital, Brooklyn, during 1922 and 1928, and superintendent of Hays Sanitarium and Park West Hospital, New York, from 1923 to 1927. From 1928 to 1936 she served as superintendent in Prospect Heights Hospital, Brooklyn, and from 1937 to 1940 she was in charge of nurses in Women's Homeopathic Hospital, Philadelphia, from which she came to Goshen.

Dr. Francisco Diaz-Valdes of Havana, Cuba, has taken over the post of intern at General Hospital in Utica.

Dr. Valdes received his degree in medicine from the University of Havana early in 1943 and since then was an intern in a Havana hospital.\*

Terminating thirty-six years' service as a member of the Board of Managers of the Mount Vernon Hospital, Richard M. Winfield has resigned as a board member and as vice procedure of the Associaboard member and as vice-president of the Association.

The board accepted the resignation "with regret" and unanimously elected Mr. Winfield an honorary member. The only other living honorary member of the board is Mrs. William H. Martens of

Bronxville.

Dr. Mark J. Schoenberg has been appointed consulting ophthalmologist at the Manhattan Eye, Ear and Throat Hospital.

Dr. Louis Lahn has been appointed Adjunct Proessor of Gynecology and Obstetrics and Assistant Attending Gynecologist at the New York Polyclinic Medical School and Hospital.

. Dr. M. F. Donnelly has been chosen as chiefof-staff at Nathan Littauer Hospital in Gloversville. Dr. Donnelly succeeds Dr. H. H. Oaksford, who has served in this capacity for the past three

Dr. Donnelly has been connected with the hospital staff for more than ten years, and has served as at-

tending surgeon.\*

The Lewis County board of supervisors has reappointed Frank Bowman, of Lowville, a member of the board of directors of the Lewis County General Hospital and Mrs. John F. Woolschlager, of Castorland, a member of the county laboratory board.\*

#### LY NOISE ABATEMENT PROGRAM SHOULD BE PART OF WAR EFFORT

Pointing out that "injury, measurable and uneasurable, from noise such as now widely attends man life is real and not a matter for speculation, irey P. McCord, M.D., and John D. Goodell, etroit, declare in the Journal of the American edical Association for October 23 that relief from ise is procurable and that effort against noise is a idely neglected but legitimate portion of over-all arfare.

Their article is a report of the Association's

ommittee to Study Air Conditioning.

In their introduction the two men say that "It a commonplace fact that the nation's present reumstances of living and working have greatly ultiplied both the quantity and the continuity I noise. At the same time justification for noise ems better established so that indignation, howver warranted, meets some disfavor. If the period f national stress may so accentuate the ill effects f noise that a disturbed people will demand and ecure relief both for the duration of the conflict nd thereafter, at least one constructive end will rave been attained...

"The acceptance of noise as an inescapable ecessity possibly reflects unintelligent complaency. A proper understanding of the established Il effects of noise and the practicability of noise ontrol would appear to warrant sponsorship of ioise abatement as a fecund war measure. surpose of this report is to assert that much current ioise is needless; that effort against noise is a videly neglected but legitimate portion of over-all variare; that methods of noise control are practial and no longer technically mysterious; and behind ome of the more publicized evils of the day, such is wilful absenteeism, may be found the insidious disturbances from noise."

The authors point out that although not all industries may be disturbingly noisy, a recent prewar publication listed 467 occupational pursuits out of 7,000 as ones clearly contributing undesirable noise output. They say that this figure fails to indicate the total probable exposure since many noise-free operations are customarily carried out in proximity to noisy ones. "As a rule," they say, "the architecture of manufacturing plants is such

as to accentuate reverberation.
"Chiefly from industrial experience, it is now accepted as established that noise produces significant deafness both on a functional and on an organic basis, that noise causes or contributes to pathologic fatigue and under some circumstances lowers the work output, Less certainly established, but probable, are the indications that noise unduly contributes to absenteeism, increases work spoilage and generally hampers the worker, and especially the new worker in job adjustment....

"It is fallacious to claim that workers become inured to noise. They may become inured on the basis of deafness, but any psychologic adjustment that may appear to take place must be reacquired on a day-to-day basis."

They say that many noisy operations in an industry may be made quiet ones with relatively little difficulty. As for noise abatement through architectural features, the two men say that "present and prospective needs inescapably require a wider application of architectural noise prevention....
"To accomplish noise privacy it becomes neces-

sary to provide two structural features: (1) a design of wall structure so as to prevent the transmission of sound from exteriors and between rooms; (2) sufficient absorption within rooms that the reverberation time will not be excessive. Contrary to some popular and pseudo architectural concepts, these are two distinct matters requiring individual

As a whole, although high-frequency sounds produce greater acoustic injury than those of low frequency, in the long run low-frequency sounds may offer greater problems because they are less

easily abated.

Dr. McCord and Mr. Goodell say that the control of noise by municipal or higher authority never has been wholly effective and never will be until the time is reached when both the public and responsible officials have acquired better concepts of the significance of noise and the measures through which noise may be eliminated or reduced to inoffensive

"Education of the public as a whole and in special groups along the necessary legislation," they say,

appears to be the key to noise amelioration."

They say that it also seems necessary to carry out educative programs for the makers or surveyors of noisy devices, and particularly for architects and builders of various structures such as homes, hotels, office buildings, and streetways. They cite as an example the need for improvement in the sound aspects of many automobile horns and other warning devices, and point to the fact that the mellow horn now used on diesel locomotives has been found to have many advantages over the shrill steam whistle.

"The continued use of noisy streetcars lends affront no longer to be tolerated as a necessary evil, except under the immediate conditions imposed by

war," the two men declare.

#### Health News

#### Industrial Health Meeting Follows Medical Education Congress

"The sixth Annual Congress on Industrial Health (sponsored by the Council on Industrial Health of the American Medical Association) will take place on February 15 and 16, 1944, at the Palmer House in Chicago," the Journal of the Association announces in its December 25 issue. "Those who expect to attend are urged to make travel and hotel reservations at their earliest convenience. These sessions follow directly after those of the Annual Congress on Medical Education and Licensure. The deans of medical schools and others interested in medical education may find it possible to attend the sessions on industrial health; a special effort will be made to induce them to do so. Official representatives of medical societies and allied organizations can attend both congresses this year without extra travel.

"One of the great obstacles to the growth of industrial medical service has been the slow development of public interest in the health and economic benefits which the physician can bring to the industrial organization. The Congress on Industrial Health, therefore, will attempt to attract greater interest from management and labor. Prominent representatives of these groups will be asked to

participate.

"Interest in the physical welfare of the working population must be maintained even after the stimulus of wartime production is over. element in postwar planning must be encouraged. The sessions of the sixth Annual Congress on Industrial Health will attempt to bring this relationship into proper focus. The congress will also emphasize the importance of physical restoration, retraining, and reemployment of the disabled, an issue which is certain to be a source of medical preoccupation for some years to come.

"Industrial health is gradually assuming greater and greater importance as an avenue for the distribution of medical service. Every physician and medical organization should recognize the trend so that the movement may be guided along dependable

scientific and educational lines."

#### Units of Civilian Physicians Commissioned by Public Health Service

THE U.S. Office of Civilian Defense announced on December 8 that 93 hospitals and medical schools scattered throughout the country have completed formation of "affiliated units" of civilian physicians which will be available to either the OCD or the Army in the event of need for setting up emergency hospital facilities in their respective areas.

Each unit is composed of 15 physicians, surgeons, and other specialists, and forms a balanced professional staff. OCD will use the units to supplement sional staff. OCD will use the units to supplement the staffs of "emergency base hospitals" located in relatively safe zones on the fringes of critical areas in case it is necessary to transfer civilian patients to these hospitals because of emergency in such areas.

The units will be called upon by the War Department to staff extemporized hospitals should there be a sudden influx of battle-front casualties, or some other extraordinary military necessity, requiring hospitals and physicians beyond the immediate capacity of the Army in any particular locality.

The OCD-affiliated units will be used for military emergency purposes only in or near the communities in which the staff resides. Their duty will be temporary and they will be replaced by Army doctors as quickly as the Surgeon General of the Army can make the necessary assignments.

Normally, all the 15 doctors of a unit are assorated with a single hospital. Each unit includes: 1 chief and assistant chief of medical services, (470 general internists, a chief and assistant chief of surp cal services, four general surgeons, two orthopsedic surgeons, one dental surgeon, one pathologist, and

one radiologist.

Physicians accepted for service in the units receive inactive reserve commissions in the U.S. Public Health Service, but will be called to active duty by the Surgeon General (USPHS) only at the request of OCD. When a unit is needed, either to staff an emergency base hospital or to assist the Army temporarily in a military emergency, the physicians of the unit will be placed on active duty for the duration of that particular emergency.

Organization of these units in selected communities will give both OCD and the Army organ ized emergency hospital staffs which can be called

upon in time of need.

Following is a list of units completed and commissioned by the Public Health Service up to October 30, 1943, arranged according to Civilian Delense Regions:

# WHERE THE APPETITE NEEDS TEMPTING...

The patient whose capacity for exercise is limited, frequently presents a peculiar nutritional problem. Appetite wanes, digestion falters and a vicious circle thereby develops.

Horlick's helps solve this problem with little, if any, tax on the digestion. This delicious food-drink offers a pleasant means of pushing sound basic nutrition and insuring the intake of "effective" food elements.

In many conditions of infection—e.g., influenza and its aftermath—where it is necessary to "push" liquids while administering full nutrition with good vitamin intake, Horlick's can be most helpful.

Horlick's is delicious whether prepared with milk or with water. The Tablets are also useful and convenient to eat at intervals during the day.

#### Clark to Head Physical Rehabilitation Section

Federal Security Administrator Paul V. McNut has announced the assignment of Dr. Dean A. Clark surgeon, U.S. Public Health Service, as chief medi cal officer of the Office of Vocational Rehabilitation to take charge of the newly established Physics Rehabilitation Section. The arrangement between these two branches of the Federal Security Agency was made by Surgeon General Thomas Parran a the request of Michael J. Shortley, director of vocational rababilitation tional rehabilitation.

In commenting upon Dr. Clark's appointment Mr. Shortley said that use of Federal funds to remedial medical treatment of the physically hands capped was authorized for the first time under th

Barden-LaFollette Act of July 6, 1943.
"Until the expansion of the Vocational Re habilitation Program under this new law," he said "there was no Federal program for this purpose although the Federal Government has long aider the States in providing vocational guidance and training for the handicapped. The addition ophysical rehabilitation greatly strengthens the program, because relatively simple surgery often materially decrease a physical handian of can materially decrease a physical handicap o

even remove or fully compensate for it."

He explained that the new vocational rehabilitation program will make an important contribution the the way offert by facilitation the analyses of the second program of the secon to the war effort by facilitating the employment of the physically handicapped and thus promoting effective use of manpower for war work.

## After You, Doctor, in the Care of Flat-Feet

When there is evidence in a customer that flat-feet are developing, we do not pretend that our knowledge is sufficient to correct or arrest such a condition. We know our part can be helpful, but prefer to have a physician or surgeon say so.

We do not believe that a mere print of the feet—the usual examination of shoe stores promoting "health" shoes is sufficient to indicate the real nature of flat-feet. We prefer to have our customers see their doctor first and then come to us when he recommends the type of shoe he wants the patient to use.

When this is done, Pediforme Footwear will do the job for which prescribed and scientifically constructed for. You may be confident of that.

#### Clark to Head Physical Rehabilitation Section

Federal Security Administrator Paul V. McNut has announced the assignment of Dr. Dean A. Clark surgeon, U.S. Public Health Service, as chief medical officer of the Office of Vocational Rehabilitation to take charge of the newly established Physics Rehabilitation Section. The arrangement between these two branches of the Federal Security Agenc, was made by Surgeon General Thomas Parran at the request of Michael J. Shortley, director of vocational rehabilitation.

In commenting upon Dr. Clark's appointment, Mr. Shortley said that use of Federal funds for remedial medical treatment of the physically handicapped was authorized for the first time under the

Barden-LaFollette Act of July 6, 1943.
"Until the expansion of the Vocational Rehabilitation Program under this new law," he said, "there was no Federal program for this purpose, "there was no Federal program for this purpose, and the Part of Company the laws aided although the Federal Government has long aided the States in providing vocational guidance and training for the handicapped. The addition of physical rehabilitation greatly strengthens the program, because relatively simple surgery often can materially decrease a physical handicap or even remove or fully compensate for it."

He explained that the new vocational rehabilitation program will make an important contribution to the war effort by facilitating the employment of the physically handicapped and thus promoting effective use of manpower for war work.

[Continued on page 320]

HIS war-winter brings its devastating blitz of respiratory ailments and arthritic flare-ups which must be treated promptly, efficiently. Two effervescent products stand out as effective agents for bringing symptomatic relief—

# Acetyl-Vess (Buffered Salt of Aspirin)

# Salici-Vess (Buffered Salics late Alkalı with Sodium Iodide)

These potent analgesic, antipyretic formulae are enhanced by the presence of alkali buffers which assure maximum tolerance and essential fluid intake. Buffer-alkali mechanism in combination with the effervescent (CO<sub>2</sub>) factor hasten absorption by decreasing emptying time of the stomach.

Acetyl-Vess—tubes of 25 tablets. Salici-Vess—tubes of 30 tablets.

Available through your prescription pharmacy or medical supply house

[Continued from page 318]

Mr. Shortley called attention to the fact that the rehabilitation program is designed to assist all physically handicapped individuals to obtain remunerative employment, except veterans with service-connected disabilities, who come under the program directed by the Veterans Administration. The program is operated by the States through their Boards of Vocational Education and their official agencies for the blind.

As a war measure, the Federal Government pays the full cost of rehabilitating war-disabled civilians. These include officers and crew members incapacitated while on war duty in the merchant marine, and members of the Aircraft Warning Service, Civil Air Patrol, and U.S. Citizens Defense Corps. For other individuals, the Federal Government pays half the cost of rehabilitation. All administrative expenses of the States in conducting approved rehabilitation programs are also met with Federal funds. Under the new statute, Federal aid may be utilized to provide all types of medical and surgical services necessary to modify a physical condition which is static and which constitutes a substantial handicap to employment. Conditions for which medical services are undertaken must, however, be of such a nature that treatment may be expected to eliminate or substantially reduce them within a reasonable length of time. Hospitalization not to exceed ninety days may also be furnished as well as prosthetic appliances essen-

tial for obtaining or retaining employment.
With Dr. Clark as chief medical officer, Mr.
Shortley said, the Physical Rehabilitation Program will be directed by a physician with both a broad training in several fields of medicine closely associated with rehabilitation work and also experience in public administration. Since 1938, Dr. Clark has been engaged in work connected with the organization and distribution of medical care. On the staff of the U.S. Public Health Service since 1939, he was assigned to the Division of Public Health Methods, National Institute of Health, until 1942; for the last year and a half he has served as chief of the Emergency Medical Section of the Public Health Service and as chief of the Hospital Section, Medical Division, Office of Civilian Defense.

A native of Minnesota and a graduate of Princeton University, Dr. Clark's background includes three years as a Rhodes Scholar at Oxford University, England, where he received the degrees of Bachelor of Arts and Bachelor of Science in physiology. In 1932, he took his medical degree at the Johns Hopkins Medical School, Baltimore. He served an internship in medicine at the Johns Hopkins Hospital; later he was assistant resident nopkins nospital; later ne was assistant resident in medicine and neurology at the New York Hospital, New York City; National Research Council fellow in neurophysiology at the Cornell University Medical College, New York City; assistant resident at the Henry Phipps Psychiatric Clinic, Johns Hopkins, and intern at Trudeau Sanatorium, Trudeau, New York.

#### Award of the Sedgwick Memorial Medal

At the Seventy-second Annual Meeting of the American Public Health Association held recently in New York City, Brigadier General James Stevens Simmons, director, Preventive Medicine Division, Office of the Surgeon General, United States Army, was awarded the Sedgwick Memorial Medal for 1943 "for distinguished service in public health."

#### Health Units for the West Indies

A large-scale demonstration of the health unit system—by which it is hoped to improve the standard of health throughout the West Indies-is being staged in Jamaica to serve as a model and training ground for twelve other schemes in Jamaica, and many more throughout the islands. The health unit, a new idea for the Colonies, is an organization which provides a small community with the means to prevent and cure disease. Its main functions are seven: health education, antenatal and maternal care, child welfare, school medical work, prevention of endemic diseases, control of endemic diseases, and sanitation. The work of the unit is carried on from a center, where a medical officer of health has his office. Clinics are held for treatment, and an important feature is a meeting-room for talks, lectures, and demonstrations. Away from the center will be branches, staffed by nurses and midwives, who will also visit the people's homes.

Village health leagues will be formed, and the center will put out health propaganda. The Jamaica Center is to have a model venereal disease clinic, and start an intensified campaign against yaws. The underlying assumption is that with good teamwork the health unit system can accomplish far more than a much larger number of doctors working independently could do; it can get into close touch with the people and can be linked with social welfare, agriculture, education, and other efforts to raise the standards of rural life in the

West Indies.—Brit. M. J.

## New Advisory Committee on Health Edu-

An Advisory Committee on Health Education has been appointed by the President of the New York Tuberculosis and Health Association in accordance with the recommendation of the Executive Committee. The appointment of the new committee brings into one advisory group Board members and other leaders in this field who already are acquainted with special aspects of the Association's health education work. It will give to the Association and to the Health Education Secretary, Mrs. K. Z. W. Whipple, the advantage of its joint counsel on the broad health education program.

Dr. Donald B. Armstrong, who for a number of years has been board adviser on health education, is chairman of the new committee. It includes also among the members, chairmen of subcommittees on health education of the several divisions of the Association who have been giving advice regarding

health education work in their respective fields.

Board members appointed to the committee are: Board members appointed to the committee are: Dr. Donald B. Armstrong, Chairman; Dr. Leverett D. Bristol, Dr. Kendall Emerson, Mrs. Walter A. Hirsch, the Very Rev. Msgr. William R. Kelly, Mrs. Ruth Logan Roberts, and Dr. Ernest L. Stebbins. The other leaders in the field who have accepted membership are: Dr. Frank J. O'Brien, associate superintendent of schools; Dr. Harry Ungerleider, chairman, Health Education Committee, Heart Division; Dr. John Oppie McCall, chairman, Health Education Committee, Dental Division; Dr. C. C. Pierce, chairman, Social Hygiene Committee, and Dr. Charles E. Lyght, director, Health Education, National Tuberculosis Association. Association.

#### Public Health Service Reorganized

Dr. Thomas Parran, Surgeon General of the U.S. Public Health Service, has announced the names of five persons to head the new bureaus and divisions set up through the reorganization of the U.S. Public Health Service by Congress on November 11. The reorganization was authorized in the enactment of a bill (S. 400)

Dr. Lewis R. Thompson, medical director serving in the surgeon general's office, has been named assistant surgeon general in charge of the new Bureau of States Services. Dr. Ralph C. Williams, formerly district director, with headquarters in New York, has been named assistant surgeon general in charge of the new Bureau of Medical Services. Dr. Rolla E. Dyer, director of the National Institute of Health, Bethesda, Md., will in addition serve as assistant surgeon general in charge of the new Bureau of Scientific Research. John K. Hoskins, senior sanitary engineer, under the new setup will become chief of the division of sanitary engineering, and William T. Wright, Jr., D.D.S., chief of dental work in the Marine Hospital Division of the Public Health Service, will become chief of the division of dentistry. All five will hold ranks comparable to an army brigadier general, it was approunced. They have been in a grade comannounced. They have been in a grade comparable to a full colonel in the Army. Mr. Hoskins is said to be the only nondoctor or -dentist to hold a rank in the Public Health Service comparable to that of brigadier general. S. 400 provides that the Surgeon General of the Public Health Service, under the supervision and direction of the Federal Security Administrator, is authorized and directed to assign to the Office of the Surgeon General, to the National Institute of Health, and to the Bureau of Medical Services and the Bureau of States Services the functions of the Public Health Service and to establish within the Office of the Surgeon General and the other groups named such divisions, sections, and other units as may be required to perform their functions.—J.A.M.A.

#### Dr. Godfrey Reappointed Health Commissioner

The gratifying news was announced December 23 of the reappointment by Governor Dewey of Dr. Edward S. Godfrey, Jr., as State Commissioner of Health, thus continuing the established custom in New York State of appointing to this highly responsible position a public health administrator

of established reputation.

This has been a tradition in the State since 1914, when Dr. Hermann M. Biggs, who had developed the New York City Health Department and had a national and international reputation in public health, was appointed State Health Commissioner, serving until his death in 1923. He was succeeded by his deputy, Dr. Matthias Nicoll, who served until 1930, when he accepted a position as Health Commissioner of Westchester County. Dr. Nicoli was succeeded by Dr. Thomas Parran, Jr., then in the U.S. Public Health Service, whose leave of absence to New York was authorized by President Hoover, and the Secretary and Under-Secretary of the Treasury Department, the late Mr. Andrew Mellon and the late Mr. Ogden Mills. Dr. Parran served until 1936, when he was appointed Surgeon General of the U.S. Public Health Service.

Thus, since January, 1914, there have been four

Health Commissioners of New York State who have served during fourteen gubernatorial terms. Two of them, Dr. Biggs and Dr. Godfrey, were continued in office by two Governors of a different party from the one who originally appointed them.

The health department of all divisions of Federal, State, and local government, has the greatest practical opportunity for promoting human well-being through the prevention of disease. If qualified and able men are to be attracted to a public health career, responsible positions in public health must be filled by career men and their tenure of office should be reasonably assured on the basis of demonstrated efficiency. The action of Governor Dewey in reappointing Dr. Godfrey as State Health Commissioner is heartening and encouraging confirmation of this fact.

Since 1908, Dr. Godfrey has held increasingly responsible public health positions, beginning with that of Superintendent of Public Health of the territory of Arizona. In 1917 he was appointed one of the District State Health Officers by Dr. Biggs. He became Director of the Department's Division of Communicable Diseases in 1920, and in 1934 was appointed Assistant Commissioner for Local Health Administration, serving until 1936, when he became Commissioner.—S.C.A.A. News

#### Gorham Is Appointed to Public Health Council

Governor Thomas E. Dewey has announced the reappointment of Dr. L. Whittington Gorham, of Albany, to the New York State Public Health Council. The term of office of council members is six

Dr. Gorham was also recently appointed a member of the Executive Committee of the State Committee on Tuberculosis and Public Health, State

Charities Aid Association.

#### Deborah Society Raises \$100,000 for Tuberculosis Fund

The Deborah Jewish Tuberculosis Society celebrated its twentieth anniversary on December 19 at the Waldorf-Astoria with a dinner in honor of its founder, Mrs. Dora Monness Shapiro. Israel Katz, president, announced that \$100,000 had been raised at the function for expansion of the society's facilities at Brown's Mills, N. J.

Messages of congratulation were received from Governor Dewey, Mayor La Guardia, Senator Robert F. Wagner, Mrs. Franklin D. Roosevelt, William Green, president of the American Federation of Labor, and Philip Murray, president of the Congress of Industrial Organizations. The society is supported by the cloak, suit, and dress industry

and by fraternal organizations.

#### War Work a Hazard to the Tuberculous

High wages paid to war workers are a lure which prompts many patients to leave tuberculosis hospitals before they have regained their health and acts as a deterrent to newly diagnosed cases accepting early treatment. As a result, the public health is jeopardized, according to Dr. Robert E. Plunkett, General Superintendent of Tuberculosis Hospitals of the State Department of Health.

Doctor Plunkett emphasized that many patients are endangering their lives and the lives of others by going into war plants, thereby exposing fellow workers and members of their families to the dis-

#### [Continued from page 322]

ease. "These beds are empty in spite of the fact that during the first ten months of 1943 there were fifty more deaths and 252 more new cases reported than in the corresponding period of 1942," he said. He added that the Department is taking steps to bring these facts to the attention of physicians, public health workers, industrial leaders, and others in order that this serious situation may be corrected.

"One evidence of the decrease in the utilization of tuberculosis hospital facilities is that in the last few months there were about 750 vacancies for adults in all county, city, and state public tuberculosis hospitals in the upstate area. This represents 16 per cent of the total beds available for adults, whereas under normal circumstances, only from 5 to 10 per cent of such beds are unoccupied at any one time.

"Of even greater significance is the observation that fewer patients known to have infectious tuberculosis are currently isolated in hospitals than formerly. In 1941, an analysis of tuberculosis cases residing in the areas under the supervision of the district state health offices showed that of those patients known to have tubercle bacilli in their sputum, about 60 per cent were then receiving hospital care and treatment. A similar study in the summer of 1943 revealed that only 40 per cent of such patients were hospitalized.

"For these people with active tuberculosis even light work is very apt to be detrimental. The least possible effect of working is retardation of eventual recovery from the disease but, for the majority, this ill-timed return to work represents nothing short of gambling with death."

#### Plan to Furnish Sanitary Engineers

The State Department of Health today made public a plan evolved in an effort to meet a serious public health problem caused by a shortage of sanitary engineers in the Department due to demands for service in the armed forces. C. A. Holmquist, director of the Division of Sanitation of the Department, announced the plan, which calls for the intensive training of civil engineers while serving in the Department, and the appointment of the first six under the program.

At the outbreak of the war fourteen sanitary engineers in key positions with the Department who were reserve officers responded to calls to active duty. Their positions were filled by promoting junior engineers. Mr. Holmquist said that eight of the present district sanitary engineers of the Department are under 38 years of age and are now being processed for commissions in the Army and probably will be called for military duty early in 1944.

"The system of training in the department for public health engineering," Mr. Holmquist said, is definitely a wartime measure, made necessary by the shortage of sanitary engineers in the country to fill the appeared and are in the country.

to fill the expected vacancies.

"The graduate engineers so far appointed will be trained in the field to fill the vacancies and to handle the public health engineering work in the districts to which they have been assigned. They will be under the supervision of sanitary engineers in adjacent districts. It was if the content of the co

districts to which they have been assigned. They will be under the supervision of sanitary engineers in adjacent districts. It was difficult to find men to fill these jobs and we canvassed practically the entire country. However, we were fortunate enough to find the eight men neeeded to carry on the work."

The men have been assigned to district offices as follows: Ringhamon.

The men have been assigned to district offices as follows: Binghamton, J. H. Bolton, of Watkins; Amsterdam, C. R. DeGraff, of Amsterdam; Poughkeepsie, J. C. Milluish, of New York City; Middletown, H. H. Boeckman, of New York City; Oneonta, H. Stemmann, of New York City; and Batavia, Burton X. Lentz, of Watsontown, Pennsylvania. Vacancies still exist in the Kingston and Gouverneur offices, but it is expected that they will be filled within a few days.

# Psychiatrist of British Army Praises U.S. Mental Tests

BRIG. J. R. Rees, chief of the neuropsychiatric service of the British Army, recently told of the technic of American doctors enabling the return to active duty of 60 per cent of a group of soldiers who in the last war would have been known as "shell-shock" cases. The American system, he said, was "far ahead of anything we have in England." Brigadier Rees further states that England has looked to the United States as "the home of progress in psychiatry." He said that America had done "magnificent work" in the last war in psychologic testing of prospective soldiers and that not only England but Germany also has borrowed largely from American procedure.—J.A.M.A.

#### History of Medicine

The Session on the History of Medicine of the Medical Society of the State of New York holds annual meetings along with the regular sections of the Society. It has had two very successful meetings, and is preparing for a third in 1944. So far, the policy of the Session has been to confine the subject of the papers presented to material related to the history of medicine in New York State. In this way, a valuable compilation of data related to New York State medicine will be gradually accumulated.

Anyone having material suitable for presentation before this session will kindly communicate with the Chairman, Edward F. Hartung, M.D., at 580 Park Avenue, New York 21, New York.

#### REVIEWED

History of Surgery. By Richard A. Leonardo, M.D. Octavo of 504 pages, illustrated. New York, Froben Press, 1943. Cloth, \$7.50.

This seems to be the first large-scale history of surgery by a medical man. It is our impression that The Story of Surgery (1939) was written by a layman (Harvey Graham). In any case Leonardo's book is more comprehensive than the latter or John S. Billings' work on the subject (1895).

An especially useful feature is the seven chapters on recent surgery in England, Switzerland, Italy, France, Germany, Austria, and Hungary.

ARTHUR C. JACOBSON

Micrurgical and Germ-Free Techniques. Their Application to Experimental Biology and Medicine. A Symposium. Edited by James A. Reyniers. Octavo of 274 pages, illustrated. Springfield, Ill., Charles C Thomas, 1943. Cloth, \$5.00.

Micrurgy is a term introduced by Peterfi (1923) for work on a microscopic scale, such as micromanipulative technic under a microscope. This book is a symposium of papers by the editor and other well-known authorities in the fields of biology, botany, and medicine; in it are discussed briefly the

machines and technics for single-cell isolation of micro-organisms, as well as the propagation of higher forms of plant and animal life (invertebrate and vertebrate) in the germ-free state. There are also excellent chapters on the application of these methods to the study of the physical chemistry of protoplasm, the in-utero infection of embryos with viruses, and the prevention of air-borne infection in the human. No mention is made of the recent work with aerosols.

E. J. Tiffany

Biomicroscopy of the Eye. Volume 1. By M. L. Berliner, M.D. Quarto of 709 pages, illustrated, including 40 pages of color plates. New York, Paul B. Hoeber, Inc., 1943. Cloth, \$17.50.

This very satisfactory work on biomicroscopy of the human eyes is the first of its kind to appear in the United States. In spite of the difficulties with which the printer and publisher had to deal during this period of international war, the volume is a very fine example of the printer's art. The great number of colored illustrations are reproduced on a soft mat finish which, to the reviewer's mind, enhances their

[Continued on page 328]

FACTS DOCTORS SHOULD HAVE ON

# WINE DIET

Discussions of wine's historical uses . . . the caloric content of wine . . . its dextrose and levulose content . . . its vitamin and mineral constituents . . . the assimilability of the ferrous iron in wine . . . etc. . . form one of the chapters of The Therapeutic Uses of Wine (a Summary). This review in monograph form has been prepared by competent medical authorities. It should be of interest to specialists in many fields as well as to the general practitioner.

THE CONTENTS INCLUDE: Sections on the actions of wine on the gastro-intestinal system, the cardio-vascular system, the kidneys and urinary passages, the nervous system and the muscles, and the respiratory system. The uses of wine in diabetes mellitus, in acute infectious diseases and in treatment of the aged and the convalescent. The value of wine as a vehicle for medication. A section on the contraindications to the use of wine. An extensive bibliography for those who may wish to pursue the subject further.

This review results from a study supported by the Wine Advisory Board, an agricultural industry administrative agency established under the California Marketing Act, and has been sponsored by the Society of Medical Friends of Wine.

A copy of *The Therapeutic Uses* of *Wine* is available on request to any member of the medical profession. Write for it, to the Wine Advisory Board, 85 Second Street, San Francisco.

#### [Continued from page 326]

usefulness. Although one does not gain the more natural appearance of highlights which is lent by the use of glossed paper, still the details are well brought out and the soft finish makes prolonged

study less fatiguing.

Dr. Berliner has arranged his material according to a comprehensive and lucid plan. He begins by discussing the various instruments and the theories of their construction and use. He then takes up in the classic order the various tissues of the eye and discusses their normal and pathologic appearances. His emphasis on the use of vital stains is worthy of special notice. Dr. Berliner's descriptions are clear and accurate. He has covered not only the commoner but also many of the more unusual conditions met with in clinical practice, and he has given due credit to those who have contributed to the subject.

Without a doubt, this volume and its companion, which is to follow, will become the standard textbooks for postgraduate work in this country. No ophthalmologist, be he novice or expert, can afford

to be without this fine contribution.

JOHN N. EVANS

Fingerprints, Palms and Soles. An Introduction to Dermatoglyphics. By Harold Cummins and Charles Midlo, M.D. Octavo of 309 pages, illustrated. Philadelphia, Blakiston Co., 1943. Cloth, \$4.00.

The authors, both professors of microscopic anatomy at Tulane University, Louisiana, have produced a classic on dermatoglyphics, a study of the patternings of epidermal ridges on fingers, palms, toes, and soles. The configurations are formed in the early fetus and they persist unchanged. Their variants exhibit differential trends among races, between the sexes, and among constitutional types. Some traits of the dermatoglyphics are heritable, hence are useful in recognizing types of twins and have promise of application in questioned paternity.

The book is immensely interesting to the biologist, geneticist, and dermatologist.

NATHAN THOMAS BEERS

An Introduction to Medical Mycology. By George M. Lewis, M.D., and Mary E. Hopper, M.S. Octavo of 342 pages, illustrated. Chicago, The Year Book Publishers, 1943. Cloth, \$6.50.

In the second edition of this book the authors have brought the bibliography up to date and have amplified many parts of the book with the very latest findings. The same clear and concise statement of facts has been continued. It is the most practical treatise in the English language on medical mycology. All the complicated nomenclature of this field has been simplified, so that it can be understood without difficulty.

It is a book that all dermatologists must have and one that many other physicians will want to bring their libraries up to the minute in mycology. J. C. Graham

Fractures and Dislocations for Practitioners. By Edwin O. Geckeler, M.D. Third edition. Octavo of 361 pages, illustrated. Baltimore, Williams & Wilkins Co., 1943. Cloth, \$4.50.

Although a small volume, this book covers the subject matter fully, emphasizing methods of treatment best applicable in the hands of the general practitioner or under conditions where modern equipment or adequate support is lacking. .

However, the author does not fail to mention and briefly analyze the most advanced ideas advo-

The descriptions necessarily must be brief, and therefore would prove insufficient for the use of the surgeons not fully trained in the treatment of these injuries.

The author's ideas as a whole are sound, and if carried out properly, should produce good results in

the treatment of such injuries.

NATHAN H. RACHLIN

Life is Too Short. An Autobiography. By C. Kay-Scott. Octavo of 348 pages. Philadelphia, J. B. Lippincott Co., 1943. Cloth, \$3.50.

This is the life story of a most extraordinary man, who began as a doctor of medicine, under his right name, Dr. Wellman, and achieved international fame as an African explorer and an expert in tropical medicine. Subsequently he assumed the name of C. Kay-Scott, lived for years in South America, explored the Amazon, was an unsuccessful farmer but a successful business executive, and gave up this phase of his protean career to go to France to study art, in which he was again to find acclaim and prominence. There is a delightful foreword by one of his sons, written in deep appreciation of the author's life and accomplishments. There is much philosophy in the book-not medical, but social, ethical, and cultural. This may make the reading not always the easiest, but the discussions are always sound and often profitable. When the book was written, the author was 72 years old and looking forward to his new adventure, which he feels certain will be "exciting". His life undoubtedly was-in many lands and in many languages and in a variety of marital environments.

JOSEPH RAPHAEL

Proceedings of the Rudolf Virchow Medical Society of the City of New York. Volume 1, 1942. Edited by the Publication Committee: Franz M. Groedel, M.D., and Bruno Kisch, M.D. Octavo of 72 pages. New York, Brooklyn Medical Press, Inc., 1943. Paper, \$1.00.

This little volume contains numerous useful contributions by a number of specialists. Doctor Mannheimer presents an interesting review of the achievements of Doctor Einhorn. There follow achievements of Doctor Einhorn. two helpful articles on the duodenal tube and the use of dyes in the diagnosis of gastric disorders. Achylia gastrica is covered in a very lengthy article by Kaufmann. Other papers on gastrointestinal disorders deal with pancreatic tumors and the salivary glands. Infectious diseases like scarlet fever and typhus are covered by several authors.

There are timely papers on phases of war medicine such as rheumatism, circulatory disturbances, trench nephritis, and neuropsychiatric findings in

combatants.

Lichtwitz has a thorough article on fatigue There are quite a few interesting case reports as well. Though one might not subscribe to all the views

expressed in this brochure, the papers are nevertheless interesting and worth reading. A. M. Babey

The Boy Sex Offender and His Later Career. By Lewis J. Doshay, M.D. Octavo of 206 pages, illustrated. New York, Grune & Stratton, 1943. Cloth,

This study is based on information obtained \$3.50.

#### ONE FOR THE PSYCHIATRIST

"Murder in a Nutshell" or just plain "Murder." Just so long as it is a murder story of some kind, the average patron of a news-stand seems to enjoy the gruesome.

For twenty-five cents, you can now spend a good part of the weekend wading through "Murder at Sunrise" in red, "Murder at Noon" in green, or "Murder at Sunset" in blue. The colors, of course,

refer to the book covers.
Says a news writer, "The stack of 'Murder at 4. P.M. (gay orange) reaches halfway to the ceiling. It won't last, though. Over the weekend it will be sold to the last copy, and on Monday a towering heap of 'Murder at Breakfast' in chrome yellow will

have its place. "While publishers announce dozens of postponements of works of non-homicidal fiction, pleading the paper shortage, murder, it seems, is not rationed.
"It's the war,' explains the news vendor, 'People want something to rest them.'"

want something to rest them.

#### AIR MEDAL FOR NEW YORK M.D.

To Lieut. William Ward Evans of New Rochelle, N. Y., goes the honor of being the first Navy medical officer to receive the Air Medal.

The medal was awarded to Lieut. Evans for his participation in hazardous flights over enemy territory while squadron flight surgeon for a Marine aircraft group in the Solomon Islands.

He aided wounded pilots and made a study of

effects of combat strain on aviators.

#### WE ARE COMING TO THIS

The War Food Administration has announced new soap formulas. These formulas prescribed by that agency, it is claimed, will not make any appreciable difference in soaps we are using, because most of the soap manufacturers have already used them voluntarily.

The new formulas require a larger use of non-fat substances, principally resins which are substitutes and which, it is insisted, do a good job in providing

lather and water softening.

#### [Continued from page 328]

through examining and treating boys in the Children's Court Clinics of New York City. There are 256 cases in the series, which covers a six-year period dealing with sex offenses in boys between the ages of 7 and 16 years. Part 1 deals with the background of the delinquent, Part 2 is concerned with his personality, Part 3 shows the outcome, and Part 4 offers the author's conclusions. Statistical tables and case study forms are included in the appendix.

This book is of value primarily to those interested

in the subject of sex offenses.

STANLEY LAMM

The Therapy of the Neuroses and Psychoses. By Samuel H. Kraines, M.D. Second edition, thoroughly revised. Octavo of 567 pages. Philadelphia, Lea & Febiger, 1943. Cloth, \$5.50.

New material has been added to this edition to present the more recent thoughts on the shock therapies, the organic psychoses, and the neuropsychiatric aspects of mental hygiene induced by

the war.

The author maintains that common sense in the treatment of mental disease is the most important factor. However, since this is a book on therapy one cannot agree with him in his curt dismissal of the psychoanalytic method of treatment of the neuroses with the assertion that the freudian doctrines are "extremely fanciful".

The book will be of value to the medical student and the general practitioner for the practical suggestions it contains for the treatment of mental

disease.

JOSEPH L. ABRAMSON

Biological Symposia. A Series of Volumes Devoted to Current Symposia in the Field of Biology. Edited by Jaques Cattell. Volume X, "Frontiers in Cytochemistry." Octavo of 334 pages, illustrated. Lancaster, Jaques Cattell Press, 1943. Cloth, \$3.50.

This book consists of a series of papers presented at the Fiftieth Anniversary Celebration of the University of Chicago in September, 1941, and the Annual Meeting of the American Association of Anatomists in April, 1942.

It is a sober, serious, and thorough presentation of the modern concepts of the problems of the action and metabolism of sex hormones and of the hormonal factors in the inversion of sex. The cautious and restricted conclusions drawn by the leading authorities in the field, as presented in this book, are in sharp contrast to the somewhat extravagant and often disorderly conclusions drawn by some authors on the basis of meager clinical data.

The book is recommended as an authoritative summary of data and interpretation on this im-

portant endocrinologic problem.

ARTHUR SHAPIRO

Fundamental Exercises for Physical Fitness. By Claire Colestock and Charles L. Lowman, M.D. Octavo of 314 pages, illustrated. New York, A. S. Barnes & Co., 1943.

This work is a supplement to and includes selections from Corrective Physical Education for Groups by Lowman, Colestock, and Cooper. It is essentially a manual for those who have to do with body development of children. In the first part of the book the need for proper body training in the young

is shown by deductions from the findings of the Army Induction Centers.

J. C. RUSHMORE

A Textbook of Medicine. Edited by Russell L Cecil, M.D. Associate Editor for Diseases of the Nervous System, Foster Kennedy, M.D. Sixth edition, revised and entirely reset. Quarto of 1,565 pages, illustrated. Philadelphia, W. B. Saunders Co., 1943. Cloth, \$9.50.

The sixth edition of this textbook presents a number of new and important changes: It contains new articles on twelve subjects not previously covered; there are thirty-one subjects which have been rewritten; there are also introductory chapters to eight groups of diseases. The reviewer calls special attention to those on diseases of the blood and on virus diseases. A very convenient addition is the table of normal values for chemical examinations. The number of illustrations, though increased over the last edition, still is less than contained in a number of other American texts. This feature is a valuable aid to students. And last, but surely not least, is the change in the format—the text has been arranged in double column. To the student this will be the most acceptable change of all.

This textbook improves with every new edition. It has one hundred and fifty-four contributors, most of whom have shown commendable restraint in their special field. This volume, whether used as a textbook or for reference, will most adequately meet the needs of the former and the immediate require-

ments of the latter.

S. R. BLATTEIS

Reconstructive Surgery of the Eyelids. By Quarto of 160 pages, Wendell L. Hughes, M.D. St. Louis, C. V. Mosby Co., 1943 illustrated. Cloth, \$4.00.

This work was presented by the author as his "thesis for admission to the American Ophthalmological Society and represents the evolvement of methods for the reconstruction of new lids along with a historic review of the previous methods."

There are ten chapters, the first five being de voted to the history and evolution of skin grafts of various types and the remainder to description of specific types of operations, concluding with those devised by the author. It is copiously illustrated and well indexed, and there are 451 references of the control of ences. It is a mighty good book for an ophthalmic surgeon to have.

E. CLIFFORD PLACE

Managing Your Mind. By S. H. Kraines, M.D., and E. S. Thetford. Octavo of 374 pages. New York, Macmillan Co., 1943. Cloth, \$2.75.
The outbox contend that a better understanding

The authors contend that a better understanding of our complaints and the mechanism by which emotions are translated into symptoms will enable one to gain control of the body, the mind, and the emotions. The reader is expected to be able to alleviate the manifestations of an emotional dis-turbance because of the better understanding of

There is no doubt that many of the explanations given by the authors will prove of value to the readers, and they will feel encouraged by the explanation of their neurotic complaints; but the reviewer doubts the ability of the average person to benefit from the material contained in the book There are too many case histories and the medical language is sometimes too technical. JOSEPH L. ABRAMSON

#### ONE FOR THE PSYCHIATRIST

"Murder in a Nutshell" or just plain "Murder." Just so long as it is a murder story of some kind, the average patron of a news-stand seems to enjoy the gruesome.

For twenty-five cents, you can now spend a good part of the weekend wading through "Murder at Sunrise" in red, "Murder at Noon" in green, or "Murder at Sunset" in blue. The colors, of course, refer to the book covers.

Says a news writer, "The stack of 'Murder at 4 P.M. (gay orange) reaches halfway to the ceiling. It won't last, though. Over the weekend it will be sold to the last copy, and on Monday a towering heap of 'Murder at Breakfast' in chrome yellow will have its place.

"While publishers announce dozens of postponements of works of non-homicidal fiction, pleading the paper shortage, murder, it seems, is not rationed.
"It's the war,' explains the news vendor, 'People want something to rest them.'"

#### AIR MEDAL FOR NEW YORK M.D.

To Lieut. William Ward Evans of New Rochelle. N. Y., goes the honor of being the first Navy medical officer to receive the Air Medal.

The medal was awarded to Lieut. Evans for his participation in hazardous flights over enemy territory while squadron flight surgeon for a Marine aircraft group in the Solomon Islands.

He aided wounded pilots and made a study of effects of combat strain on aviators.

#### WE ARE COMING TO THIS

The War Food Administration has announced new soap formulas. These formulas prescribed by that agency, it is claimed, will not make any appreciable difference in soaps we are using, because most of the soap manufacturers have already used them voluntarily.

The new formulas require a larger use of non-fat substances, principally resins which are substitutes and which, it is insisted, do a good job in providing

[Continued from page 330]

Collected Papers of the Mayo Clinic and the Mayo Foundation. Edited by Richard M. Hewitt, M.D. A. B. Nevling, M.D., John R. Miner, James R. Eckman, and Katharine Smith. Vol. 34, 1942 (published July, 1943). Octavo of 999 pages, illustrated. Philadelphia, W. B. Saunders Co., 1943. Cloth, \$11.

In spite of the war, the 1942 volume contains 183 articles, many of which are of special interest to the general practitioner, diagnostician, and general surgeon. Especially to be commended are articles on the newer therapeutic advances, such as the use of promin for tuberculosis; sulfa drugs, penicillin, and gramacidin for infections; heparin and dicoumarin for thrombosis; and vitamins. Many worthwhile articles dealing with the alimentary tract, genitourinary organs, ductless glands, blood, circulatory organs, skin, syphilis, head, trunk, extremities, vision, the nervous system, radiography, physiotherapy, anesthesia, and gas therapy, make this volume, as were its predecessors, the outstanding yearly postgraduate necessity.

M. A. RABINOWITZ

The Role of Nutritional Deficiency in Nervous and Mental Disease. [Res. Publ. Ass. Nerv. Ment. Dis., Vol. 22.1 Editorial Board, Stanley Cobb. M.D., chairman. Octavo of 215 pages, illustrated. Baltimore, Williams & Wilkins Co., 1943.

This book consists of a group of articles in the nature of a symposium. As usual in such contributions there is quite a bit of repetition, as regards introductory remarks and references to the literature, by each contributor. Thus there is a lack of the continuity found in a book written by one author. It is more like a medical journal, with independent articles and some duplication.

The book is divided into two parts. The first portion of the book contains contributions from the fields of the fundamental sciences, consisting of experimental work on vitamin deficiencies and pathology as relates to the central and peripheral nervous systems, as well as their interpretation, The second portion of the book deals with clinical observations and therapy.

There are a few articles that bear no direct relationship to the subject matter. However, there is much material available that makes this little book a very good addition to the medical library.

Morris Ant

Rehabilitation of the War Injured. Edited by William Brown Doherty, M.D., and Dagobert D. Runes. Octavo of 684 pages, illustrated. New York, Philosophical Library, 1943. Cloth, \$10.

The editors have presented a symposium including numerous prominent articles by various

cluding numerous prominent articles by various authors, many of the articles being reprints from

current medical and surgical journals. The field of neurology and psychiatry is well covered, and is followed by over two hundred pages on reconstructive and plastic surgery. This is followed by a section on physiotherapy, occupational therapy, and vocational guidance; also the legal aspects of rehabilitation.

The authors have endeavored to present to the profession the up-to-the-minute methods of treatment which might be employed in the reconstruction work which it is even now necessary to carry out in many of our government hospitals.

For those interested in this branch of medicine and surgery, the publication should prove a valuable addition to their library.

#### POSTWAR TRAVEL PLANNING

While 1944 is not likely to see the resumption of pleasure travel on a very extensive scale, recent travel statistics at least offer hope to the future tourist.

The inveterate traveler, at present absorbed in war work, may take heart for travel lanes of the world are being rapidly extended as war supplies are delivered to stations once mere dots on the map. He will enjoy wider horizons and faster schedules when he again goes pleasure cruising.

Air schedules proposed for 1948, and earlier, from New York, include 2 hours and 40 minutes to Bermuda; 8 hours and 12 minutes to Mexico City; 13 hours and 48 minutes to London; and 23 hours and 12 minutes to Cairo. Proposed trips across the Pacific, the Atlantic, and the Mediterranean

appear like ferry rides.

Some 429,000 persons traveled to Europe from

the record travel year of 1937, the United States in the record travel year of 1937, to say nothing of those journeying to other places, near and far. Now with buses about to sprout helicopters, plans for more airplanes and larger

capacity ships with greater speed, the number of eager Marco Polos who, come peacetime, will take to the world's travel trails cannot be estimated.

Then, too, keep your eye on the new "jet" engine for greater private air travel and cheaper automobile transportation.

#### "SIDE-DOOR PULLMANS" TAKES ON A NEW MEANING

The term "side-door Pullman" no longer exclusively describes an unloaded boycar utilized by a hobo on his travels.

This term has now attained respectability, for in 1943 the most modern type of Pullman palace car made its appearance—with side doors! Travelers in the armed forces have been making the acquaint-

ance of the new luxurious "side-door Pullman."

The general traveling public will begin to know and appreciate the streamline modern design of this wartime railroad innovation when peace comes.

#### VITAMIN A AND DRIED EGGS

According to the studies of Drs. Harry L. Fevold and Howard D. Lightbody of the Western Research Laboratory of the Department of Agriculture, virtually no vitamin A is lost in spray-drying eggs.

However, at each temperature studied, the vitamin was lost in storage. At 15 degrees Farenheit this loss occurred in nine months, and within three months at 98.6 degrees.

Losses can be checked by small amounts of wheat-

germ oil.

CINCINNATI, U.S.A.

### Calcium and Vitamin D in pleasant-tasting, easy-to-take form-

### CALCI-DELTA TABLETS

(Dicalcium Phosphate and Vitamin D)

### Lederle

TO MEET the exceptional metabolic demands for L calcium made upon the body at certain timesduring pregnancy, lactation, early childhood-Lederle now makes available "Calci-Delta Tablets Lederle." These new tablets serve as an excellent source of calcium, phosphorus and Vitamin D. They are easily chewed and swallowed and their pleasant flavor disguises the rather disagreeable taste typical of calcium salts.

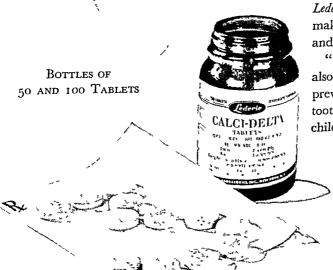

If the mother does not receive an adequate calcium, phosphorus and Vitamin D intake during pregnancy and lactation, either in the diet or in supplements thereto, she may suffer from tooth decalcification and other forms of calcium deficiency. Likewise, the fetus may be adversely affected, if enough of these elements are not supplied for its structural growth. "Calci-Delta Tablets

Lederle" are in a palatable form, which makes them appreciated by pregnant and lactating women.

"Calci-Delta Tablets Lederle" art also especially suitable for children to prevent rickets and promote normal tooth and bone development in early

childhood.

SS MADISON AVENUE, NEW YORK, N. T.

The causes of "sterility" are so manifold that no one type of treatment can reasonably be expected to succeed in any high percentage of cases. However, in view of the definitely physiologic action of Nutri-Sal, as well as its complete safety and simplicity in use, it may be conscientiously recommended under the following circumstances. . . . 1. During the routine investigation of infertility. 2. In instances where the husband's semen is slightly sub-normal with respect to count and motility. 3. When exhaustive studies

Nutri-Sal, a vaginal douche powder containing glucose in a Ringer's-type base, is used in warm water solution, prior to coitus. It acts therapeutically by counteracting inimical genital secretions and providing nutriment for sperm viability and motility.

have failed to reveal any gross pathological condition responsible for failure to conceive.

# STAYING Power

Aggressive little atom of American bird-life, the beautiful Humming-bird flies so fast that the eye can scarcely follow. It operates its wings with such incredible power and speed that it is enabled to stand still—literally poised in air—as it gleans the nectar of flowers.

Similarly, the ability to remain "poised" over painful areas is attributed to small quantities of EUCUPIN, the local anesthetic-analgesic agent. Like the Humming-bird, Eucupin possesses a remarkable kind of staying power—the kind that controls pain for longer periods than any other agent, the effect lasting for hours and even for days.

Eucupin has been especially formulated for particular indications. They are described in a literature booklet, which, together with samples, is available to physicians on request. Please indicate form desired.

Supply: Aqueous and oil solutions for infiltration; ointment and suppositories; tablets for solutions to be applied topically.

### VI-SYNERAL VIVI IN DROPS

TWO YEAR RESEARCH ACHIEVEMENT

A stable, comprehensive, non-alcoholic, multi-vitamin preparation

Each 0.6 cc. (as marked on dropper) provides . . .

Vitamin A	•	•	•			4000 U.S.P. Units
Vitamin B,	•	•	•	•	•	l Milligram
Vitamin B,	•					0.4 Milligram
Niacinamide	•		٠,			4 Milligramŝ
Vitamin .C		•	• `			25 Milligrams
Vitamin D						400 U.S.P. Units

CONTAIN NO ALCOHOL

#### A MODERN FORMULA

**Built on Newer Concepts of Infant Nutrition** 

Milk, both human's and cow's, fails to furnish optimum levels of all needed vitamins. Most infants, reports one prominent pediatrician (J.A.M.A. 120:12, p. 193), can benefit from supplementary supplies of Vitamins B<sub>1</sub>, C, D, Niacin and possibly other B Complex factors... as milk, at best, furnishes only the bare minimum of these nutritional essentials.

VI-SYNERAL VITAMIN DROPS help to assure an optimum vitamin intake for infants—at a surprisingly low cost of about 4c per day. The Drops are readily accepted and well tolerated even by very young infants, also suitable for children and adults. Mix perfectly with milk or formula, fruit juices, soups, cereals, puddings.

marked dropper.

Available in 15 cc. bottles, with

- Liberal potencies
  Contain no alcohol
- Vitamins are stable
- Economical
- Do not affect taste of foods

Sample and literature upon request.

### IN IMPAIRED FAT DIGESTION

Degalol, the original chemically pure deoxycholic acid, is the constituent of human bile which is chiefly concerned with the emulsification of ingested fats.

When bile secretion is deficient, or totally lacking as in biliary fistula, the administration of Degalol assures not only digestion and

absorption of food fats but also of the fatsoluble vitamins A, D, E, and K.

When fatty foods prove intolerable in the absence of cholecystic pathology, Degalol usually relieves the postprandial distress and permits of liberalization of the diet.

Supplied in boxes of 100 1½ grain tablets.

Riedel - de Haen, Inc., New York 13, N. Y.

"On the whole," says Carlson†, "we can trust Nature further than the chemist and his synthetic vitamins."

The nutritional response obtained with *natural* Vitamin B Complex therapy cannot be duplicated by any combination of synthetic vitamins, according to investigators.

BEZON depends on Nature for its components—it is Whole Natural Vitamin B Complex, concentrated to high potency from natural sources—no synthetic vitamin factors are added. Only Whole Natural Vitamin B Complex contains all 22 B vita-

mins. In prescribing BEZON, the entire Vitamin B Complex is assured —an important fact inasmuch as Vitamin B deficiencies tend to be multiple.

BEZON is the only Whole Natural Vitamin B Complex which contains one milligram of natural thiamine, two milligrams of natural riboflavin, together with all the remaining members of the B complex, concentrated in one capsule or two tabules.

Supplied in bottles of 30 and 100 capsules; 60 and 200 tabules.

Samples and literature available on request

### KONDREMUL

(PATCH)

(Chondrus crispus) containing 55% mineral oil. Encourages regular elimination,

provides a smooth, fecalsoftening action without irritation or griping.

It mixes thoroughly with the fecal mass, resists enzymic and thermal action within the

bowel and maintains an even dispersion all the way through the gastrointestinal tract.

Kondremul is available in three forms:

**Kondremul Plain**—for simple constipation. Permits smooth, voluntary elimination.

Kondremul with non-bitter Extract of Cascara\*—for atonic, senile and pregnancy constipation.

Kondremul with Phenolphthalein\* (2.2 grs. phenolphthalein per tablespoonful)—for the obstinate case.

\* Caution: Should not be used when abdominal pain, nausea, vomiting or other symptoms of appendicitis are present.

S()) (Frewer The ORIGINAL ENTERIC-COATED TABLET OF THEOBROMINE SODIUM ACETATE to control frequency and severity of

attacks in CARDIOVASCULAR AND RENAL DISEASES and to prevent EDEMA

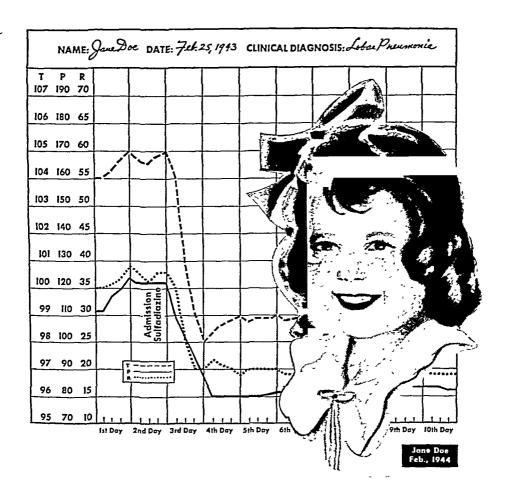

Clinical experience and studies have proven the value of Theobromine Sodium Acetate in certain Cardiovascular and Renal Diseases. In Angina Pectoris, used adequately, it permits more work by the individual without developing precordial pain or distress. As one of the most effective Xanthine Vasodilators it helps increase the available blood supply to the heart and kidneys to increase the efficiency of these organs.

It has also been found an effective aid in treating and preventing Edema of Cardiac or Renal origin. The enteric coating (especially developed for Thesodate) permits larger doses without the drug's contact with the Gastric Mucosa.

AVAILABLE IN various potencies with or without Phenobarbitol. Literature on request.

### LEDERLE

### The Drug of Choice For Pneumonia

### SULFADIAZINE STANDS AS A SOLID BULWARK BETWEEN THE PATIENT AND THE MYRIAD DANGERS OF WINTER'S MOST DANGEROUS DISEASE.

"Over-all" mortality statistics from published series of cases in hospital practice bear eloquent testimony to the effectiveness of this sulfonamide in pneumonia—Flippin, Rose, Schwartz and Domm<sup>1</sup>, 11%; Finland, Strauss and Peterson<sup>2</sup>, 11%; Dowling, Hartman, Sugar and Feldman<sup>3</sup>, 11.3%;

Billings and Wood<sup>4</sup>, 1.3%; Abernethy<sup>5</sup>, 10.7%; Ensworth, Kalkstein, Barefoot, Liebmann and Plummer<sup>6</sup>, 10.9%; Flippin, Schwartz and Domm<sup>7</sup>, 10.3%; Dowling, Hartman, Feldman and Jenkins<sup>8</sup>, 8.1%; Shackman and Bullowa<sup>9</sup>, 13.4%; Browne, Marvin and Smith<sup>10</sup>, 1%.

#### Invaluable in the desperate early hours of pneumonia:

Exceptionally low incidence of nausea and vomiting.

High blood concentration, readily attained following oral dosage.

Low proportion of acetylated sulfadiazine in the blood.

Gradual decline of blood levels following discontinuance of the drug.

Ready penetration into ascitic, pleural and cerebrospinal fluids.

Greater solubility of acetyl sulfadiazine in aqueous solutions than sulfadiazine itself.

Rapidly increasing solubility of both sulfadiazine and acetyl sulfadiazine in the urine as the pH is raised in an alkaline direction.

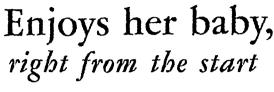

Well tolerated intravenously in 5% solution, also subcutaneously in 0.5% solution.

Sulfadiazine possesses a literature background which for authority and scientific weight is unmatched by that of any other sulfonamide, in the treatment of

- Pneumococcus Pneumonia
- Hemolytic Streptococcus Pneumonia
- Staphylococcus Pneumonia
- Friedländer's Bacillus Pneumonia
- Postoperative and Other Mixed Pneumonias

'Dexin' does make a difference

#### COMPOSITION

Dextrins . . 75% Mineral Ash . 0.25% Maltose . . 24% Moisture . . 0.75%

Available carbohydrate 99% 115 calories per ounce

Literature on request

From the moment a baby is given his first 'Dexin' feeding, mealtimes are happy times for both baby and mother.

'Dexin' helps to assure uncomplicated infant feeding because its high dextrin content (1) diminishes intestinal fermentation with resultant reduction in distention, colic and diarrhea and (2) promotes the formation of soft, flocculent, easily digested curds.

Formulas modified with 'Dexin' are palatable, and not excessively sweet. 'Dexin' is readily soluble in hot or cold milk. Supplied in containers of 12 ounces and 3 pounds.

### OF LOCAL CHEMOTHERAPY

in Oro-pharyngeal Infections

ONE White's Sulfathiazole Gum Tablet chewed for one-half to one hour promptly initiates a high topical salivary concentration of locally active (dissolved) Sulfathiazole and maintains throughout the maximum chewing period an average concentration of 70 mg. per cent. Two tablets increase salivary concentration approximately 20%.

An average adult chewing a total daily dosage of 8 tablets, for as long as an hour each, should develop a blood level of Sulfathiazole not greater than one milligram per cent. Thus White's Sulfathiazole Gum provides an effective means of sustained local chemo-

therapy—with minimal risk of the untoward reactions frequently associated with intensive systemic use of sulfonamides.

Indications: "septic sore throat"; acute tonsillitis, pharyngitis; infectious gingivitis and stomatitis caused by Sulfathiazole-susceptible micro-organisms; peritonsillar abscess; prevention of local infection secondary to oral and pharyngeal surgery (e. g. tonsillectomy).

In packages of 24 tablets, sanitaped in slip-sleeve prescription boxes—on prescription only. White Laboratories, Inc., Pharmaceutical Manufacturers, Newark 7, N. J.

### YOUR DIRECTIONS are carried out in detail

To give directions is part of your contribution to the care of your patients. To follow your directions is the patient's responsibility.

At Saratoga Spa your directions for chronic cases of heart, circulatory and rheumatic disorders can be carried out in detail. In its restful environment your patients submit to regime and to your prescription-for-living. Relief from home distractions and pressures prepares your patient for the full benefit of your continuing medical direction. Saratoga Spa was planned for your use. Around its world-famed, naturally carbonated mineral waters, New York State has organized superb facilities for the use of practicing physicians. The Medical Staff of the Spa is non-practicing. It only oversees the treatments prescribed by you or the local specialist you choose for your patient. Open all year.

For professional publications of The Spa, physician's sample carton of the bottled waters, with their analyses, write W. S McClellan, M.D., Medical Director, Saratoga Spa, 155 Saratoga Springs, N.Y.

Specialists in Ethical Vitamin Specialties

# Rapid and Sustained REDUCTION of stomach hyperacidity

When *Greamalin* is taken, acidity in the stomach is reduced promptly. This is followed by a slow and persistent antacid effect

With *Creamalin* no secondary rise in secretion of acid gastric juice occurs. Moreover, there is no danger of producing alkalosis.

Creamalin often induces rapid healing of peptic ulcer when employed with an ulcer regimen

Creamalin Tablets are convenient to carry and easy to take—and they are palatable.

Supplied in bottles of 50 and 200 tablets.

### WHEN YOU NEED A GOOD SUPPORT

FOR REDUCIBLE HERNIA - may we suggest the advantages of "custom-made" Protection, designed to meet the described needs of each particular case? Physicians, who know from experience, can tell you that Rice "custom-made" Supports for reducible HERNIA are truly different and that our methods are dependable. With dozens of different styles, shapes and types of pads at our disposal and with a full realization of our responsibility to those who put their faith in us—we respectfully offer our services for your approval. Descriptive literature and measurement charts on request.

WILLIAM S. RICE, Inc., (Lock Box 101), ADAMS, NEW YORK BRANCH SUPPLY AND FITTING OFFICES BUFFALO, N. Y.—ROCHESTER, N. Y.—PITTSBURGH, PA.

### Design for Hematinie Therapy

FFFECTIVE COMPOSITION: Liver residue ... 3 gr., Ferrous Sulphate, Exsiccated (U.S.P.)... 3 gr., Thiamine HC1 ... 1 mg., Riboflavin ... 0.66 mg. and Niacin ... 10 mg.

### ENDOGLOBIN

REC U.S PAT OFF.

### Tablets

Each tablet provides the raw materials universally accepted for hemoglobin regeneration, plus the raw materials for the biochemical mechanism in which hemoglobin functions.

**CONVENIENCE:** Easy to take... pleasantly flavored for chewing or swallowing.

FCONOMICAL: Budget-priced to permit protracted medication, usually required in hematinic therapy... cost the patient only a few cents a day.

DOSAGE One or two tablets, Available, at prescription pharmathree times a day, after meals. Cres, in bottles of 40 and 100 tablets.

Samples and literature sent to physicians upon request

AN Effective BARRIER

Dompetent clinical investigation has established the effectiveness of a properly fitted occlusive diaphragm. Attention, however, should be directed to the need of not only providing for the protection but also the comfort of the patient, in order to assure continued use of the diaphragm.

Examination of the "RAMSES"\* Flexible Cushioned Diaphragm reveals that:

- 1. The dome is made of velvet-soft pure gum rubber. It will not induce irritation.
- 2. The patented rim construction provides a rubber cushion which inhibits discomfort from spring pressure and provides a broad unindented surface for contact with the vaginal walls.
- 3. The coil spring used in the rim is flexible in all planes permitting adjustment to muscular action.

A carefully controlled manufacturing process builds lasting qualities into the "RAMSES" Flexible Cushioned Diaphragm, With proper care it will give long service.

"RAMSES" Flexible Cushioned Diaphragms are available in sizes from 50 to 95 millimeters in gradations of 5 millimeters. They are carried in stock by all reliable pharmacies.

Complete professional information will be sent to physicians on request.

### -and her same Cream Farina, too

JUST about a year after Mr. J. K. Polk had been inaugurated as President of the United States, Heckers' Cream Farina began its career.

The general practitioners of that day found out very soon how easily digestible, and how nourishing, it was. They approved it. And in no time, Heckers' Cream Farina was known as a first solid food for babies.

Modern babies love it just as much as their grandparents did. But there's this difference

—it's even better for babies nowadays, because it's enriched with Vitamin B<sub>1</sub>, niacin and nutritional iron. It's the same delicious heart of the wheat—with the scientific improvements favored by modern dietitians.

#### Next on the child's menu-H-O OATS

It's only a step from the easily assimilated Cream Farina to the body-building proteins of H-O Oats, and it is a

step most children are glad to take. Because H-O Oats are not only nourishing, they have a special pan-toasted flavor that children like and go for.

HECKERS' Cream Enriched FARINA

A PRODUCT OF THE BEST FOODS, INC.

# Active vs. PASSIVE

In local inflammations, passive hyperemia or congestion retards healing. An increase in the circulation from the affected area is, therefore, desirable.

An important advantage of Numotizine in the treatment of inflammation is its ability to increase local circulation in both directions, thereby assisting the natural healing process.

The slow, steady release of guaiacol, beechwood creosote and methyl salicylate from the improved Numotizine base stimulates local circulation and produces systemic analgesia for a period of 8 hours or more from a single application.

Numotizine is indicated in chest conditions, sprains, bronchitis, glandular swellings, furunculosis, etc.

Supplied in 4, 8, 15 and 30 ounce resealable glass jars.

Numotizine is ethically presented - not advertised to the laity.

#### Glaucoma as a Cause of Blindness

Of the 120,000 and more blind people in the United States, some 18,000 to 20,000 are blinded by glaucoma, and the chronic cases outnumber the acute by about ten to one. The early recognition of glaucoma is therefore of the greatest importance. Such early recognition is the subject of a paper by Dr. Harry S. Gradle, to be found on page 391 of this issue, which deserves careful reading by all general practitioners.

Early glaucoma of the chronic type may be symptomless. These patients may therefore never see an oculist during their preglaucomatous stage or during the early years of their chronic disease. But during this time they may consult their family physicians for other reasons. It is therefore important for general practitioners to recognize the fact that any patient past the age of 30 years is a glaucoma suspect unless found otherwise

#### Says Dr. Gradle:

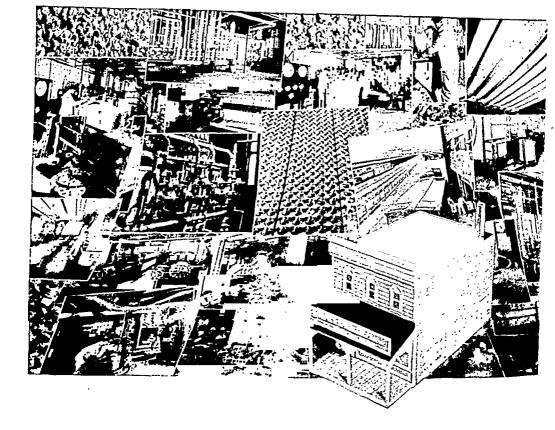

"It is a well-known fact that when chronic glaucoma is detected early, the ravages of the disease can be prevented in a fairly high percentage of cases, provided that the patient is faithful in respect to treatment and observation. But who is to detect it early? Obviously, the ophthalmologist. The general practitioner may suspect the existence of the condition, but lacks the necessary armamentarium and experience for accurate diagnosis before permanent damage has been done. A small percentage of nonmedical refractionists falls into the same class. The individual may have become thoroughly glaucoma-conscious through the fairly widespread publicity campaign, but the majority of such have a mental and not an ocular hypertension,"

The factor of greatest importance is that patients in the glaucomatous age group should be seen by an oculist. If this fact is recognized by the general practitioners it should be possible to reduce the toll of blindness from this cause to a considerable extent.

"All patients seeking ophthalmic advice have something wrong with them, either subjectively or objectively; otherwise they would not come to us for help. Among those people, glaucoma is found to be present in between 1 and 2 per cent, and consequently every ophthalmic patient (past the age of 30 years) is a glaucoma suspect, unless proved otherwise. And the negative proof is sometimes more difficult than the positive," says Dr. Gradle.

But even if the patient consults his oculist, the early diagnosis of chronic glaucoma is not without its pitfalls: for

"A pre-glaucomatous eye is one that does not present a definite pathologic picture, but does vary sufficiently from the absolute normal to arouse suspicion. Subjectively there are no symptoms. Objectively, the absolute depth of the anterior chamber may be somewhat less than the eye of the patient would indicate, or the angle of the anterior chamber is so acute as to border on the lower limits of the normal. From our goniometric measurements we believe that an angular value of less than 7 degrees is pathologic. The pupillary reactions are normal, albeit somewhat slow. There is no pathologic cupping of the disk, nor other visible evidence of intraocular pathology. The visual fields, both peripheral and central, are normal, as is dark adaptation. However, upon instillation of a mydriatic, the intraocular pressure increases 12 or 15 or 20 mm. Hg, but is easily controlled with miotics. Other provocative tests may or may not be positive. As can be seen, the majority of evidence justifying a diagnosis of pre-glauroma is on the negative

### WILLIAM JONES, PH.G.

When the doors of the Jones Pharmacy opened for business many years ago, young Mr. Jones, then just out of pharmacy school, had some definite ideas about the manner in which a prescription department should be conducted. He knew all about fresh crude drugs, and he could triturate, macerate, and percolate with the best of them. He provided sparkling glassware, and his finished prescriptions were things of beauty. He operated very successfully and the doctors liked to have him do their compounding.

Things have changed since that day when Mr. Jones opened his store. For example, along about 1923 quite a commotion was raised over something called Insulin, discovered by a couple of fellows up north. Mr. Jones immediately established an Insulin department. He was quick to realize, however, that the tons of equipment required for grinding pancreas glands and proc-

essing them through a complicated series of extractions, concentrations, and purifications had no place in his store. Mr. Jones's Insulin'is manufactured in Indianapolis, miles and miles away.

The production and standardization of Iletin (Insulin, Lilly) in its various strengths and modifications is but one of the many contributions Eli Lilly and Company has made toward the improvement of Pharmacist Jones's service to the medical profession.

Lilly ELI LILLY AND COMPANY . INDIANAPOLIS 6, INDIANA, U. S. A.

operation is not feasible, for absorption of nutritional materials is then too seriously curtailed to adequately maintain nutrition. This is the main reason why jejuno-ileitis must be treated medi-

Resection of the diseased segment is rarely indicated. Ileocolostomy, with exclusion of the involved segment, is effective in the vast majority of cases. Secondary operations have often revealed instances of healing of the diseased shortcircuited area. There was no mortality in 54 cases treated by ileocolostomy, with exclusion of the involved segment. Ileocolic resection resulted fatally four times in 23 such operations. Postoperative diarrhea is common because the intestinal fluids empty more directly into the colon. This is not to be confused with the pathologic diarrhea of disease. Lucid studies of this nature serve to make medical tasks simpler and easier in the cases of diseases as complicated and as little known as regional ileitis.

201 United Office Building Niagara Falls, New York

Editor, NEW YORK STATE JOURNAL OF MEDICINE Dear Sir:

I read your Editorial, "Evolution" on page 143 of the January 15, 1944, issue with keen appreciation of how close you were hewing to the line of thought that must be coursing through many medical minds

When you have considered the possibilities of what industrial medicine—and political medicine—and preventative medicine—and the practice of medicine by hospitals—and the influence of the big insurance carriers on fee-schedules-can do to the postwar practice of medicine by a private physician; you will have jockeyed your reasoning processes to about where the airplane pilots in the armed forces reached long ago: i.e., that there will be too many applicants for the jobs available.

The 5,000 excess of medical graduates over normal years, plus the 'steen thousands of medical

refugees from every country in Europe, before, during, and after World War II is leading to but one thing: the unprecedented exploitation of the medical profession.

There is but one answer The Supreme Court of the United States has accepted the view that we are a trade. No declaration was necessary. Much has been made of the fact that the Supreme Court of the United States made no affirmative pronouncement on the point. The fact of the matter is that the trial could not have proceeded unless it had agreed to the contention that the practice of medicine is a trade

Hospitals, and insurance companies, and politicians, and labor unions, and professional philanthropists, would stop in their tracks if a group of doctors should apply for and receive a charter in the A. F. of L. The sooner we do that, the sooner we will begin to get somewhere.

RICHARD H. SHERWOOD

December 28, 1943

Dr. Peter Irving, Editor NEW YORK STATE JOURNAL OF MEDICINE Dear Dr. Irving:

Dr. Oswald R. Jones, Chairman of Regional Committee No. 3 (New York) of the War-Time Graduate Medical Meetings, has requested that we submit the enclosed schedules of programs to you.

This is a movement for the further mobilization of the finest medical teaching talent in the direction of the service hospitals; however, it is not exclusively a service affair, as civilian doctors in regions where programs are to be offered will be invited to attend and participate and it is the desire of all concerned that the civilian medical profession take part in the program.

Weekly programs have been presented at Camp Shanks and the Grand Central Palace for several months and have been most enthusiastically received by all who have attended. We should greatly appreciate your announcing these future courses in the New York State Journal of Medicine.

With many thanks. Cordially yours, EDWARD L. BORTZ, M.D.

SCHEDULE OF COURSES OF INSTRUCTION TO BE GIVEN AT GRAND CENTRAL PALACE, 480 LEXINGTON AVENUE, NEW YORK CITY

Time: 8:30 P.M. Date Speaker Jan. 7 Dr. Albert Van- The More Frequent Aller-(Repeated der Veer cies Jan. 14) Jan 21 Dr. Harold E. B. Significance of Normal and

(Reprated Jan. 28)

Pardee Abnormal EKG Tracings rather than the positive side. Even a three-hour tension curve may show no abnormalities.

"How, then, can we confirm the existence of such a condition as pre-glaucoma? Only by willful disobedience of the patient and long-continued observation. I have the records of three patients in whom I made the diagnosis of pre-glaucoma three to six years ago. They were given weak miotics to use and were warned of possible danger, although evidently not impressively enough. All were faithful with the miotics for three months up to two years, during which time no evidence of a developed glaucoma could be found on repeated examination."

We urge that all general practitioners familiarize themselves by means of any of the standard texts with the symptomatology of acute and chronic glaucoma in the interest of these thousands of patients who are on the way to blindness from this cause. Early recognition and competent investigation by an oculist remains, in the present state of our knowledge, the only hope for many.

#### Pneumonia Deaths

The recommendations of the New York City Pneumonia Advisory Committee, which will be found on page 409 of this issue, stress the importance of knowledge of the bacterial etiology of the disease. Deaths from primary pneumonia in the city "have far exceeded the average number of deaths which would be expected during this period of the year." The number of bacteriologic examinations of sputum performed by the Bureau of Laboratories of the Department of Health," states the report, "have been insignificant in comparison with the number of reported deaths."

Since the advent of the sulfonamides "it has been disappointing to note that . . . . there has been a gradually decreasing interest on the part of physicians in determining the bacterial etiology of pneumonia in their patients." Such bacteriologic examinations are an absolute necessity when patients

"do not respond favorably to 18-24 hours of adequate sulfonamide therapy." But to await the results of such therapy increases the difficulty of ascertaining the etiologic agent.

The availability of specific therapy for pneumonia has not by any means decreased the importance of sputum examinations, careful, repeated, physical examinations, the necessity for adequate nursing care, rest, oxygen therapy, maintenance of fluid balance and the treatment of pleural pain with codeine. It is recommended because of the shortage of nurses that all cases of pneumonia be hospitalized as early as possible.

Physicians are urged to study the complete report of the Advisory Committee in view of the seriousness of the large increase in the morbidity and mortality from this cause.

### Regional Ileitis

The last word on the subject of regional ileitis has not yet been spoken or written. Since this entity was first described its clinical features have been clarified and the indications for medical or surgical treatment have been more definitely outlined. This subject, however, still has ramifications and complexities which future studies should unravel and simplify. Recent surgical experiences shed further useful light on the treatment of this disease.

It is perhaps not sufficiently realized that there are two forms of regional ileitis. One is a strictly localized form, limited to the terminal 4 or 5 feet of the ileum, which is amenable to surgical therapy. The other is a more generalized enteritis, with more of the ileum included, a form calling for medical and not surgical treatment.

Since the therapy of the two types is so different, it is of the utmost importance to be able to differentiate between them. It must be further realized that jejuno-ileitis occurs frequently, and a thorough search for its presence should be made by careful intestinal studies. If surgery seems indicated after such studies seem to eliminate jejunal involvement, a thorough exploration of the small intestine should be performed at operation to make certain that the lesion is limited to the terminal ileum. Only after this operative search has been performed can therapeutic surgery be actually instituted. There may be many feet of normal intestine between the diseased jejunum and the diseased ileum, a fact of which the operator must be fully cognizant. If the disease extends too far, a short circuit

#### EMOTIONAL FACTORS IN ALCOHOLISM

EDWARD B. ALLEN, M.D., White Plains, New York

THERE have been many scientific and ob-L jective approaches to this problem, but such intellectual investigations, while often accurate, have never seemed to give sufficient consideration to the feelings, to the subjective content, or even to the dynamics of those afflicted. Statistics, knowledge of pathology, warnings, awareness of the inevitable consequences of alcoholism, and even repeated personal experiences have produced relatively little effect. Thus far the most successful efforts from a therapeutic standpoint have come through religious conversion or some form of ecstasy, replacing the patient's previous anxiety and restlessness. In other words, what creates an ability to stop drinking is that which causes an alteration in the feelings of those who have been so afflicted.

Let us study these factors in greater detail. There are many people who enjoy a glass of beer or wine, a cordial, a cocktail, or even hard liquor in moderate amounts. These people drink to alleviate temporarily the twinges of conscience or the uncertainties about meeting responsibilities. They are at least complacent and philosophic, if not entirely content with life. They do not wish to change their emotional status to any great extent. If they are convivially minded, they wish to remain that way. They do not desire to use their convivial pursuits as the vestibule to prolonged forgetfulness. They are sufficiently stable to feel content in the presence of their fellow beings. They are not obsessed with inferiority feelings or fears of what their associates know or may be thinking about them. When they are restless, their means of seeking relief are not overcompensations that result in either physical or mental disability. They are classified as moderate drinkers.

When we come to the alcoholics, we find a different situation. The alcoholics are addicted to hard liquor, preferably whiskey, diluted in their more refined moments and straight when realities become too much for them. They often enjoy conviviality with their friends, but such quasi adjustments are not satisfying. They are restless and ill at ease. Two or three drinks pep them up and make them feel more confident.

If there has been no undue stress for them during the day, they may remain content to stay in the

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 6, 1943. From the New York Hospital, Westchester Division, White Plains, New York vestibule of forgetfulness, but more frequently they have an inner urge they cannot control that ushers them, accompanied by an alcoholic nepenthe, into the inner sanctum of complete oblivion.

It is our purpose to learn what the alcoholic is trying to escape from and why. If the sword of Damocles were suspended above his head by a hair, if his tissues were infiltrated with metastatic carcinoma, or if, as the victim of a revolution, he faced imminent arrest and execution, no one would be astonished if he turned for relief to the temporary forgetfulness engendered by alcohol, or if he attempted to extend that forgetfulness into complete surcease from his tangible dangers through prolonged unconsciousness by means of continued indulgence.

But if he came from stable stock, if he had had a satisfactory college career, if his marriage had produced healthy issue, if he had achieved recognition in his chosen profession and had then taken to excessive drinking, he would have been immediately subject to critical and derisive comment, betraying perplexity and surprise on the part of his admonishers. He would be the only one aware of the fact that latent fears and sensations, even more terrible because of the subtle disguise and obscurity of their cause, were arising within him and producing greater distress than the externalized ones so readily apparent to others. It is one of the greatest tragedies of life that we can all share externalized dangers with others, but that internalized ones we have to face more or less alone. The alcoholic feels as justified in drinking under such conditions as he does when the causes are obvious, but he is as handicapped in explaining such phenomena to his associates as they are in understanding them, because of his repressions and his ignorance of their functioning.

The alcoholic is responsible for the attitude directed toward him by well-integrated individuals. He refuses to betray how insecure he feels within for fear of ridicule or contempt from without. He overcompensates and disguises by boasting of the attractive features of his alcoholic exploits and of his ability to extract satisfaction out of them. He tries not only to awaken our sympathy but at the same time to awaken our envy of him in posing as a man of the world and the possessor of a secret sophistication into which we can never be initiated. How often we hear him exclaim, "You

Dr. Peter Irving Medical Society of the State of New York Dear Dr. Irving:

A number of physicians and dentists in New York State have responded to the request issued by the New York State Historical Association for early equipment to be used in furnishing model offices of years ago. These office reconstructions will be established in the museum of the Association at the Cooperstown headquarters, immediately after the

Although some material has already been given, additional articles are needed, for there are many phases of both professions which are not represented, as yet.

Any physician or dentist who has any anti-quated instruments can give to the Association

articles which are too valuable or too historical to be of salvage quality. Even published works are requested, for changes in methods can be traced through the published word. Any doctor or dentist should be proud to have his gifts represented in this museum display which will be a permanent record of

the early days of his profession.

All donors will be given due credit and the articles will be placed with the exhibit already assem-

Donations or communications may be addressed bled. to Miss Janet R. MacFarlane, New York State Historical Association, Cooperstown, New York, or to Dr. T. Wood Clarke, 7 Cottage Place, Utics,

New York.

Sincerely yours,

T. WOOD CLARKE

Editor, New York State Journal of Medicine Dear Sir:

There is a critical need for medical and surgical supplies that may lie hidden and forgotten in your office: discarded or tarnished instruments, surplus drugs, vitamins, infant foods. Collected, packaged, sent to the Medical and Surgical Relief Committee, they can play a vital role in its program of medical relief for the armed and civilian forces of the United

Surgical instruments and medicines are sought after by physicians and pharmacist's mates of our Navy—are hungrily snatched by the medical corps of our Allies. The work of war-zone hospitals and welfare agencies is too often crippled by the lack of medical supplies. Community nurseries in this country, refugee camps abroad, cry out for vitamins and baby foods for their ill-nourished charges.

In the pages of this JOURNAL you may have read about the Committee. It has supplied over 900

sub-hunting and patrolling ships of the Navy with emergency medical kits; equipped battle-dressing stations on battleships, destroyers, and cruisers. The Committee's roll-call of medical requests—not one of which has been translated and requests—not one of which has been turned away—reads like a world geography: the Fighting French in North Africa and Tahiti; the Royal Norwegians in Canada and Iceland; the West Indies; South and Central Africa; China; India; Great Britain; Yugoslavia; Greece; Syria; Russia; Alaska; and, of course, the United States United States.

To meet the demands that pour into headquarters, the Committee needs all types of instruments, especially clamps, scalpels, forceps, and all kinds of drugs, from iodine to sulfa products. By contributing what you can be sufficient to the contribution what you can be sufficient to the contribution of the contributi ing what you can spare, you will help speed another shipment of sorely needed medical aid.

Very sincerely yours,
JOSEPH PETER HOGUET, M.D., Medical Director

#### EMOTIONAL FACTORS IN ALCOHOLISM

EDWARD B. ALLEN, M.D., White Plains, New York

THERE have been many scientific and ob-Liective approaches to this problem, but such intellectual investigations, while often accurate, have never seemed to give sufficient consideration to the feelings, to the subjective content, or even to the dynamics of those afflicted. Statistics, knowledge of pathology, warnings, awareness of the inevitable consequences of alcoholism, and even repeated personal experiences have produced relatively little effect. Thus far the most successful efforts from a therapeutic standpoint have come through religious conversion or some form of ecstasy, replacing the patient's previous anxiety and restlessness. In other words, what creates an ability to stop drinking is that which causes an alteration in the feelings of those who have been so afflicted.

Let us study these factors in greater detail. There are many people who enjoy a glass of beer or wine, a cordial, a cocktail, or even hard liquor in moderate amounts. These people drink to alleviate temporarily the twinges of conscience or the uncertainties about meeting responsibilities. They are at least complacent and philosophic, if not entirely content with life. They do not wish to change their emotional status to any great extent. If they are convivially minded, they wish to remain that way. They do not desire to use their convivial pursuits as the vestibule to prolonged forgetfulness. They are sufficiently stable to feel content in the presence of their fellow beings. They are not obsessed with inferiority feelings or fears of what their associates know or may be thinking about them. When they are restless, their means of seeking relief are not overcompensations that result in either physical or mental disability. They are classified as moderate drinkers.

When we come to the alcoholics, we find a different situation. vestibule of forgetfulness, but more frequently they have an inner urge they cannot control that ushers them, accompanied by an alcoholic nepenthe, into the inner sanctum of complete oblivion.

It is our purpose to learn what the alcoholic is trying to escape from and why. If the sword of Damocles were suspended above his head by a hair, if his tissues were infiltrated with metastatic carcinoma, or if, as the victim of a revolution, he faced imminent arrest and execution, no one would be astonished if he turned for relief to the temporary forgetfulness engendered by alcohol, or if he attempted to extend that forgetfulness into complete surcease from his tangible dangers through prolonged unconsciousness by means of continued indulgence.

But if he came from stable stock, if he had had a satisfactory college career, if his marriage had produced healthy issue, if he had achieved recognition in his chosen profession and had then taken to excessive drinking, he would have been immediately subject to critical and derisive comment, betraying perplexity and surprise on the part of his admonishers. He would be the only one aware of the fact that latent fears and sensations, even more terrible because of the subtle disguise and obscurity of their cause, were arising within him and producing greater distress than the externalized ones so readily apparent to others. It is one of the greatest tragedies of life that we can all share externalized dangers with others, but that internalized ones we have to face more or less alone. The alcoholic feels as justified in drinking under such conditions as he does when the causes are obvious, but he is as handicapped in explaining such phenomena to his associates as they are in understanding them, because of his repressions and his ignorance of their functioning.

The alcoholic is responsible for the attitude directed toward him by well-integrated individuals. He refuses to betray how insecure he feels within for fear of ridicule or contempt from without. He overcompensates and disguises by boasting of the attractive features of his alcoholic exploits and of his ability to extract satisfaction out of them. He tries not only to awaken our sympathy but at the same time to awaken our envy of him in posing as a man of the world and the possessor of a secret sophistication into which we can never be initiated. How often we hear him exclaim, "You

don't know anything about it unless you have drunk yourself."

He will tell you of his misdemeanors as though they had positive values. He will disclose facts about himself of which you are willing to be tolerant or about which you have learned to have some appreciative understanding, but there are many others about which he remains silent. You elicit little more than, "It was a sorry mess." Even when relating his past history, he is so perturbed about what he may inadvertently disclose that he gives you a disconnected account that is vague and rambling. He has a convenient amnesia for the factors about which he is most sensitive. When he is through and you attempt to review the information he has given, you find yourself at a loss to put the facts in proper chronologic sequence. You find he has related the times he was clever in circumventing and getting the best of others, but you have little evidence with which to dwell upon his personality inferiorities. There are as many lacunae in his narrative as there are lakes dotting the map of Finland.

Surprising as it may seem, he will frequently discuss his psychosexual maladjustments in an apparently frank manner. But there is increasing evidence of camouflage as he proceeds. He will boast too freely of his virility and of his amorous conquests, but at the same time he will reveal a contempt for women in general except for his mother and possibly his wife or sister. Yet he will betray an irritability at some of their personality traits and thus disclose his marked ambivalence toward even those most dear to him. He likes them when they contribute to his comfort and gratify his narcissistic desires, but he really has little use for them otherwise. He will show you pictures of his children and gifts he has made for them in the occupation department of a mental hospital. This helps him to convince you of his sincerity. Later you learn that the pictures were sent by his wife without his solicitation and that he influenced others to contribute the greater share in the fabrication of the gifts. But soon further evidence is forthcoming that his real attitudes and feelings fail to escape his lips. He will tell you long before you have time to ask that he is "no damn homosexual" and that he has always hated perverts. Yet it seems inconsistent that he has been especially subject to their advances and has lived in an atmosphere where they flourish. There are many exceptions to these reactions among the alcoholics, but the general behavior pattern is as described.

While he will discuss psychosexual problems as disclosed above, he is more apt to be strangely reticent about his conflicts with the law or his flaunting of what constitutes socialized and civic authority. He rarely volunteers any accounts of such experiences and minimizes their significance. We get more tangible evidence of his automobile accidents and drunken brawls from the numerous scars on his body than from what he spontaneously relates.

We must be aware of these defense mechanisms and learn how to penetrate them if we are to be of aid to him in better understanding himself. But we must also be aware of his extreme sensitivity and avoid too direct or forceful an approach. The alcoholic knows far better than we our own limitations. He soon learns that we are also on the defensive in pointing out his difficulties. He knows that when we preach to him or admonish him with evident assurance, we are overcompensating. We must refrain from any selfrighteous or "I-told-you-so" attitude. He is aware that our irritability and anger are only means of covering up our ignorance. He has already learned this from his father and those who play such a role toward him in a symbolic form. The more neutral our attitude, the less display of feeling and especially undue interest, the better. Let the facts of disconcerting situations, arising under your care, speak for themselves, but let your patients know that you are aware of these facts. Be understanding, but not sorry for them. Remember, we have yet to prove that the reason we are not all alcoholics may be biologic rather than moral.

It is most disconcerting and sometimes perplexing to try to understand how the alcoholic can often abstain for long periods and then unexpectedly, at least in accordance with our philosophy of life, suddenly imbibe. But further study and observation reveals this: as long as the alcoholic is content within, he can with comparative ease refrain from drinking. Drinking is a matter of relatively little concern to him when things are going according to his liking and he is under no strain and in no situation in which his weaknesses will be revealed in competition with others.

When we try to study the situations under which the inebriate is most able to remain sober they appear at first somewhat paradoxical in character. Of course it is apparent that he is going to be more complacently abstinent when he is able to create a favorable impression without too great conscious effort. It will also be true if the possibility of any element of failure can be justified by an alibi which will appear consistent to others. Frequently it is just because he has such an alibi that he remains sober.

For example, the alcoholic is able to create a favorable impression by appearing honest and sincere in looking for employment. He easily

arouses sympathy in this manner. His friends wonder how he can keep sober and remain cheerful when everything would appear to be conspiring to keep him out of employment. But they little known the quality of his feelings hidden within. The thing which is troubling the alcoholic is what he is going to do when he gets the employment. Then he will be forced to stand on his own feet, to compete with others, to buckle down to a routine that is not to his liking, and, what is worse, the only way he can elicit any sympathy or admiration now is by sticking to his job, something he does not wish to do.

After he has held this job a few weeks or months, he ceases to attract any further attention to himself and life becomes humdrum. But getting drunk again serves his strongest desires. It not only gets him out of a situation that he dislikes, but it also stirs up commotion and comment about him, which he has missed. It also prevents his having to offer the true explanation of his weaknesses to his friends—namely, that he is not competent to make the sacrifices necessary for success. It is easier to attribute it to the false one of too great a craving for alcohol.

When you can get an alcoholic to be honest about himself, he will tell you that he cares little for the taste of alcohol or for the joys of drinking per se but that he is anxious for its effect. I have had alcoholics admit that when emotionally distressed they have had to force liquor down their throats, often in spite of frequent regurgitation, and that they would have been as satisfied if they could have had it instilled up their rectums or injected under the skin. The craving for alcohol in the alcoholic is more a craving for the habit pattern of reaction which has offered him relief from his inferiority feelings in the past than for any anticipated sensuous satisfactions of the palate in the present.

.; ;; ;;

ئىرى ئارى ئالەر I have stressed only a few of the emotional factors associated with the problem. To enumerate all of them and their integrated complexities would be as hopeless a task as trying to effect a complete psychoanalysis.

Dr. Adolph Meyer feels that a life situation for every psychopath is possible, although it is difficult at times to find the proper life situation.

I believe that we can include the alcoholic in the same category. Consequently, in this paper I wish to present some case material which will offer evidence of the factors enumerated above and illustrate in some degree at least what it is that spells success or failure in the future life of the alcoholic after he has left the hospital.

## Case Reports

The following case reports are those of three patients who were treated by me in the New York Hospital, Westchester Division, for alcoholism, without psychosis.

Case 1.—Mr. F. A. E., a lawyer, aged 33 years and single, was referred to the hospital because of excessive drinking over a period of fifteen years, finally resulting in embezzlement of money from his legal clients and an altercation in a cheap hotel.

His deceased father, a self-made man with little schooling, had become chief counselor for a large railroad system. His mother, in her middle seventies, is a timid, sensitive woman who has always been overprotective and oversolicitous of the patient, in a nagging manner.

Mr. E. showed a marked timidity in early years, largely engendered by his mother's emotional attitude, unchecked by the more stable but too busy professional father. When his mother made him wear "sissy clothes," he retaliated with temper tantrums. She tried to isolate him from the usual boys' recreations because she hated to see him grow up. Consequently he ran away from children's fights and was teased by his playmates. When he tried to assert himself by running, swimming, or climbing trees, he was spanked. He was always punished for trying to be like others of his age and of his social milieu. He cried easily, even in his twenties, when disappointed. He felt more secure with his mother, although he never admired her as he did his austere, undemonstrative father, whom he feared. He matured at the age of 12, when he was taught

the means of autoerotic gratification by his play-

mates, a practice that was continued moderately

into his adult years. In unsuccessfully trying to break away from the feminine dominance of his

mother, he had not tried to facilitate the process by

any strong emotional ties to any other member of

her sex.

When he entered college at 18, drinking first became a problem for him. Later he drank and gambled so extensively that he was asked to leave, but he was reinstated and controlled his inferiority feelings sufficiently to graduate fourth in his class. This timid, sensitive youth now entered law school to please his father but without any particular desire or interest. A year later he was rewarded with a trip around the world. This only helped to inculcate in him a desire for rewards before he had obtained any stabilizing objective. But he returned from this trip, which was punctuated by incapacitating drunkenness, to graduate from law school. As soon as he started to compete with others in the legal profession, the old inferiority feelings that had arisen in earlier years with his playmates were revived, and he drank, lost many positions, and later embezzled from his friends to pay excessive gambling debts. When his father died, his mother became more possessive. His only relations with women were with prostitutes and such intimacies had to be stimulated by liquor.

He came to the hospital on the advice of friends. During his residence there, he learned two things: first, that he must break away from his mother-dependence, and, second, that he was not sufficiently well endowed emotionally to try to emulate his father as a lawyer. When he left the hospital six months later, this was forcefully brought home to him by his having to seek relief from his sensitiveness and fears in alcohol, after only two weeks' work as a clerk in a law office. Even later, as a salesman, he lacked any competitive spirit, but he was not under the close scrutiny of others, so he refrained from drinking. Although geographically separated from his mother, he still maintained his dependence by receiving a small sum from her weekly for room and board.

In 1939, he became actively connected with "Alcoholics Anonymous," an organization of alcoholics who offer mutual assistance to one another to stop drinking, and at once a change for the better was noted in his attitude although he gave the hospital credit for having initiated this attitude. A few months later he returned to the hospital and talked before a group of physicians about how both the hospital and "Alcoholics Anonymous" had helped him, although their efforts were entirely independent of each other.

On February 9, 1943, a note was received from him which stated that he took his last drink May 9, 1939, and that he had been employed in a legal position but under supervision from December, 1939, until August, 1941, when he entered the Navy, later to become a lieutenant. He had been married since March 10, 1941, "apparently successfully." This case presentation illustrates the fact that after a patient leaves a hospital for treatment as an alcoholic, he may resort to drinking again for a time but with continued effort may finally make good.

Case 2.—Mr. P. W. J., an insurance manager, legally separated from his wife, came to the hospital willingly on the advice of a former alcoholic patient to seek relief from his alcoholism of eleven years' standing, which had resulted in increasing financial incapacity.

His father, who was deceased, had been alcoholic but dominant and successful. His mother was living. She was unemotional, introverted, and religious. In this case the patient had had difficulty adjusting to an older brother who was successful but was considered an intolerant total abstainer by the patient.

Life was at first happy for this patient, but he soon learned the value of temper tantrums in getting what he wanted from his mother. When he started to attend school, the other children teased him because of his short stature, his protruding upper teeth, and his receding lower jaw. His first obvious feelings of inferiority were developed. Later he stubbornly resisted a dentist's effort to produce better occlusion. He matured at the age of 14 and passed through an autoerotic period without conscious conflict. He began to drink in college. Shortly after he graduated, at the age of 22, his father died. He entered the latter's insurance business and worked under the direction of his "intolerant" older brother, with varying degrees of success, for eleven years. He at once increased

his alcoholic indulgence, and this became excessive following his marriage at the age of 23. The birth of a son the following year added to his responsibilities. His drinking led to a legal separation from his wife and to the breaking of his business association with his brother when he was 33. During the next two years he had two positions, but they were soon terminated because of his alcoholism. An institutional residence of a month and contacts with various physicians affected little relief. He frequently returned home to his mother for comfort and advice.

In the hospital he was generally content. He was passive. He appreciated that the longer he remained the better he felt. In the hospital he was associated with other patients who had as marked inferiority feelings as his own. He conceived the idea, under some suggestion, that for him or any other alcoholic to be successful it would be necessary for them never to drink again. He believed he had a talent for writing. He developed his ideas about alcoholism in a paper. He was a voluntary and helpful crusader in the hospital among the other alcoholics, who agreed that his remarks were pertinent. He admitted to his hospital physician that he considered himself a little superior to the other alcoholics, or at least wiser than they. This gave him a feeling of comfort. When he left the hospital after six months' residence, he remained comfortable. He had his paper published anonymously. Later he also returned to the hospital and addressed a group of physicians the same evening as the patient mentioned in the first case history.

On January 22, 1943, a letter was received from the patient's brother which stated, "I am certain that he has not taken a single drop since he left White Plains five years ago. He has completely rehabilitated his entire life, is married again, to a fine woman, and now has a young son. He is working for me and doing splendidly." A similar letter was received from the patient. It should be noted that when the patient stopped drinking, his brother no longer appeared intolerant.

Case 3.—Mr. H. T. N. F., a chemist, aged 33, single, came to the hospital because of chronic alcoholism complicated by anxiety symptoms and gastrointestinal distress.

Mr. F. was of mixed English and Jewish stock. He had many relatives who were alcoholic or nervous. His father, who was dead, had been nervous and excitable, but through persistent application he had become a college president. His mother has remained nervous and depressed throughout her life.

The patient's birth was difficult. He soon presented a feeding problem and has been subject to attacks of gastroenteritis with diarrhea all his life. Small for his age, he was self-conscious, solitary, and he refrained from competitive sports with others. He had temper tantrums and night-mares.

Masturbation had continued from childhood. At the age of 7 he indulged in oral sexual play with an older girl and developed lasting feelings of guilt. He resented the family affection for a younger brother. When he was 12, he began to read to excess, to daydream, and to insist upon smoking. He attended public high school rather than a preparatory academy, as he felt more comfortable with boys with fewer financial resources. He entered the college of which his father was president, but he took no advantage of this relationship. When he was 18, his younger brother died. Mr. F. was disappointed when he did not get the anticipated added attention, for his mother was depressed. He disliked his father's relatives on the grounds that they were too Jewish. He also resented his mother's domineering and possessive attitude.

Starting at the age of 12, he had a series of operations for herniae, a tonsillectomy, an appendectomy, and finally, at 26, an operation for a left varicocele followed by a prostatitis, doubtless the result of an acute gonorrhea a few years previous. He desired to follow in his father's profession as a scientist, although his interests were more crudely mechanical.

His alcoholism began when he was 17. He discovered he was less shy and more comfortable with others after indulgence. This delayed his college graduation, led to a jail sentence for driving when intoxicated, and prevented any successful occupation. He would get in touch with his mother when in difficulty, and she would come to his financial assistance. He finally went to a general hospital for a nonspecific colitis, and then entered the Westchester Division of the New York Hospital because of the associated alcoholism and neurotic symptoms. He had also a history of repeated mild depressions.

In the hospital he learned to control his attacks of anxiety, to exert more control over his depressive moods, and to appreciate the emotional cause of his gastrointestinal symptoms. But it took several months for him to accept his further limitations and to realize the necessity of refraining from alcohol because of them. He was in residence for ten months.

As he improved he was allowed to make extended visits away from the hospital. It then became apparent that he was not qualified to follow in his father's footsteps as a scientist or even to become a successful commercial chemist. It was also necessary for him to learn the advisability of keeping away from his neurotic mother. He was taught to accept a less pretentious but more comfortable role in life. He gave up his aspirations for a high salary and a luxurious habitation. A compromise for his scientific and mechanical interests was effected in his obtaining a position in the optical department of a large city store. He has held this position for nearly five years and has been advanced in salary. He remained abstinent until about two years ago, when he married. Then he became discontented with his employment and started to drink again, but moderately. He has occasionally called at the hospital for advice and has continued to make a satisfactory marital adjustment and to remain employed. When this patient increased his responsibilities through marriage, he again had difficulties of adjustment which caused him to feel insecure.

A review of these three case histories shows that the alcoholic can make an adjustment if he will accept his limitations and live in accordance with the restrictions which they place upon him. Each case of alcoholism presents its own individual problem, which makes it difficult and inadvisable to generalize. The mechanisms in each instance vary. But the three patients whose histories we have outlined with special attention to the emotional factors involved came from approximately the same cultural, social, and intellectual levels of society. While each of these patients handled his problem somewhat differently, there were certain causative factors that were common to all. In each instance the patient had a successful father, whom he was trying to emulate. This was too great a task for his qualifications. The first two effected a compromise by continuing in the same employment that their fathers had pursued, but they accepted subordinate roles. The first, until he entered the Navy, functioned as a lawyer, but in an assistant capacity and under close supervision. The second returned to his deceased father's insurance business, but accepted a less responsible role under his brother and was able to obtain the latter's approval when he stopped drinking. He also became better adjusted emotionally after his divorce and subsequent marriage to another woman. The third patient made a satisfactory adjustment to a different form of employment from his father's as long as he accepted his limitations and worked under supervision. But as soon as he complicated his social and instinctive life with marriage, he returned to drinking as a solace and is not satisfactorily adjusted. These patients have done better when they have accepted subordinate roles and worked under supervision than when they have tried to be directly responsible for their activities.

They have all been able to break away from an early dependency on their mothers and to marry. The mother in each case had assumed a dominant and solicitous role. She appeared to compensate for any lack of opportunity she had to shower affection on her successful and busy husband by giving it to her inferior, alcoholic son. She hated to see him grow up. In youth she indulged him in his temper tantrums and started giving him his way to conciliate him and keep him within the bonds of her affection. The alcoholic sees these mechanisms in his mother in later years, but they have become habit-forming and he cannot break away from them. The mother offers the comfort of an assured dependence, while at the

same time she awakens resentment. Consequently the alcoholic develops an ambivalent attitude toward her. The mother wants to keep him away from other children in his youth, and in later years seems more content to have him associate with women of such questionable standards as to preclude marriage, rather than to form too amorous intimacies, however conventional, with those of his own social level.

As regards the father, he is generally so busy with his successful pursuits that he has little time to give his son. The father entrusts the son's early care to the mother or the servants and then in later years is surprised to find that his son is not like himself and that he has dissimilar interests. The father has been strengthened and tempered by facing the stern realities of life and by learning how to meet them through his own efforts. He has felt that his son should be shielded from similar laborious tasks and necessities. He does not want his son to have to go through what he has experienced. But the father forgets that in sheltering the son and in giving him opportunities for which he has not exerted himself in any way, he has left him a weakling and a novice in any competitive effort.

The patient who can be helped—that is, the patient who is sufficiently intelligent and willing to be helped-must be made aware of these factors. He should be taught to think about them without becoming emotionally upset. He should be made aware of the necessity of seeking some occupation or position in which he can feel content about his exertions and in which they are not attended with ever-disturbing conscious effort. I believe he should be emancipated from his parents as much as possible, made to stand on his own feet, and taught to succeed through his own effort. If married, he should face that obligation and not seek to escape it through divorce as he has escaped so many other obligations through alcohol.

And in closing I offer to him and to you the statement of Sir Horace Walpole, "Life is a tragedy to those who feel, a comedy to those who think."

#### Discussion

Dr. Albert B. Siewers, Syracuse, New York—I wish to thank Dr. Allen for the privilege of discussing his paper and to express the pleasure which I derived from reading it—I found, as he was developing his thoughts on the emotional factors in

alcoholism, that they were very similar to my own I am of the conviction that alcoholism is always an emotional problem and should be studied and attacked as such. This problem shows the same wide range in individuals with mental problems who are not alcoholic. It is a symptom of an illness, and the handling of the problem should be directed against the basic disease.

It has been my experience that these individuals have strong oral traits. As adults, they are fond of discussion, singing, and tobacco-smoking, and they have gastrointestinal complaints. While many of them are often men and women of some accomplish ment, the majority display a rather typical lack of ambition or at least the absence of a concrete plan for living. Usually their jobs do not carry with them a great deal of responsibility. It is well known that many display latent homosexuality, which has been encouraged by an almost uniform type of mother whose emotional attitude was one of overindulgence, spoiling, and pampering This leads to a feminine identification with a paucity of common masculine traits, such as aggression and direction of purpose. In addition, they prefer and are more at ease in a masculine type of environment In their relationships with the opposite sex, these patients display poor adjustments, best seen in a weak heterosexual drive. They show an inability for maintaining normal relationships with socially accepted women.

Therapeutic approaches have been scientific in procedure. The religious approach or the Alcoholic Anonymous has some ment, and good results can be looked for in those who are essentially psychoneurotic. The schizophrenic patients are definitely a greater problem. Recently I had an opportunity to watch the "conditioned-reflex treatment" in a patient who for years had been refractory to institutional treatment and to religious and psychotherapeutic approach by competent Where the latter had completely psychiatrists. failed, the conditioned-reflex treatment succeeded in altering alcoholic habits and, apparently, has in some mysterious way given the patient some insight into his conflicts. Still more recently some good results of Alcoholics Anonymous have been The great reservoir of chronic alcoholics is found in the courts

Miller\* reviews the subject and stresses a threepoint program consisting of medical treatment, psychotherapy, and social reorientation and rehabilitation. His methods are quite ingenious.

In spite of all treatments, however, the most sensible approach is to obtain knowledge of the underlying psychopathology so that the psychiatrist may aid the patient in appreciating emotional insight. To quote Paul B. Brooks in his "Dr Jones Says" column in the Health News. "But it's like a dog with a tin can tied to his tail; the faster he runs the more commotion there is to escape from. If the dog's got sense enough he'll stop when he comes to somebody he knows is his friend and let him untie the can"

# THE POSTCONCUSSION SYNDROME: PROGNOSIS AND EVALUATION OF THE ORGANIC FACTORS

PETER G. DENKER, M.D., New York City

THOUGH all neurologists can readily attest to the frequency with which cases of the "postconcussion syndrome," or "post-traumatic encephalopathy," are encountered in practice, too little factual data as to the prognosis in these patients are available. As one reviews the voluminous literature on this subject, one is struck by the comparatively few studies of a follow-up type in so important a subject. There is still too much difference of opinion between capable men on the cause of these often prolonged symptoms, and it was with the hope of possibly shedding a bit more light on this controversial matter that the present study was undertaken.

Such a follow-up study of 100 consecutive cases seen by the author in the past twelve years of practice has been attempted. Only patients who had sustained a "cerebral concussion" are included in this group, care having been taken to evclude the more severe brain injuries—such as contusion-with focal neurologic signs on examination, skull fracture, as evidenced by x-ray or bleeding from the ears, mouth, or into the spinal fluid, and subdural or epidural hemorrhages. In other words, these were the typical cases so frequently seen, where a careful neurologic examination reveals nothing of significance, yet a head injury has been sustained and the complaints of headaches, dizziness, nervousness, etc., are prominent. Furthermore, all cases were excluded from this study if there was any question of litigation or compensation, or if there seemed to be any important source of mental conflict, which might introduce a possible psychic factor in the prolongation of symptoms. It was the distinct desire of the author to exclude as far as possible, all cases of so-called "litigation neurosis," so that a true picture of the course of events in those cases uncomplicated by possible psychogenic conflict, could be charted. Another study of a similar group of cases, where the element of litigation or compensation is a relevant factor, is now in progress. Practically all of the head injuries in this series resulted from the carelessness or misfortune of the patient—falls in homes, automobile accidents in which the patient had been at fault, and falls on slippery, icy pavements were the predominating causes.

#### Data

There were 58 women and 42 men in the series. The higher ratio of the female sex was probably due to the exclusion of those cases where the compensation or litigation element was a factor, since the latter occur more frequently in the course of masculine employment. In 12 of the cases there was no loss of consciousness whatsoever; in another 8 cases there was only momentary "stunning." The remaining 80 patients were unconscious for varying periods of time, all short, and none for longer than one hour. There was a wide variation in the age of these people, the youngest patient being 8 years old, the oldest 67 (see Table 1).

TABLE 1 .- 100 Cases of Cerebral Concussion

Ages	Cases
8-20	6
21-30	12
31–4041–50	21 26
51-60	20
Over 60	15

The symptoms complained of were remarkably similar: headaches, dizziness, and a heterogenous group of "nervous" changes, such as irritability, weakness, difficulty in concentration, insomnia, antisociability, hyperacusis, etc. These latter symptoms, if taken alone, bore a strong resemblance to the usual complaints of the neurotic and have been aptly named "nervous instability" by Symonds.1 Unlike the neurotic, however, in many of these cases, the patient did not stress these vaguer symptoms, but complained chiefly of the headaches or dizziness so that one often had to get the more complete picture of personality change from the wife or husband or a business associate before one could properly appreciate the severity of emotional change that had occurred. Trifling irritations, which previously had been of no concern, now produced marked distress and emotional upheaval. A previously affectionate husband would become a cross, surly, and unreasonable individual, lose his temper easily, or beat his child over some slight misdeed. Motion pictures or the radio no longer afforded the customary enjoyment; the "noise" was too distressing. Normal social desires seemed to be lost, friends tolerated for a brief visit, rather than welcomed, and their departure expectantly awaited. Women as well as men frequently complained of an inability to play

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 6, 1943. Associate Attending Neuropsychiatrist, Bellevue Hospital, New York City.

same time she awakens resentment. Consequently the alcoholic develops an ambivalent attitude toward her. The mother wants to keep him away from other children in his youth, and in later years seems more content to have him associate with women of such questionable standards as to preclude marriage, rather than to form too amorous intimacies, however conventional, with those of his own social level.

As regards the father, he is generally so busy with his successful pursuits that he has little time to give his son. The father entrusts the son's early care to the mother or the servants and then in later years is surprised to find that his son is not like himself and that he has dissimilar interests. The father has been strengthened and tempered by facing the stern realities of life and by learning how to meet them through his own efforts. He has felt that his son should be shielded from similar laborious tasks and necessities. He does not want his son to have to go through what he has experienced. But the father forgets that in sheltering the son and in giving him opportunities for which he has not exerted himself in any way, he has left him a weakling and a novice in any competitive effort.

The patient who can be helped—that is, the patient who is sufficiently intelligent and willing to be helped-must be made aware of these factors. He should be taught to think about them without becoming emotionally upset. He should be made aware of the necessity of seeking some occupation or position in which he can feel content about his exertions and in which they are not attended with ever-disturbing conscious effort. I believe he should be emancipated from his parents as much as possible, made to stand on his own feet, and taught to succeed through his own effort. If married, he should face that obligation and not seek to escape it through divorce as he has escaped so many other obligations through alcohol.

And in closing I offer to him and to you the statement of Sir Horace Walpole, "Life is a tragedy to those who feel, a comedy to those who think."

#### Discussion

Dr. Albert B. Siewers, Syracuse, New York—I wish to thank Dr. Allen for the privilege of discussing his paper and to express the pleasure which I derived from reading it. I found, as he was developing his thoughts on the emotional factors in

alcoholism, that they were very similar to my own. I am of the conviction that alcoholism is always an emotional problem and should be studied and attacked as such. This problem shows the same wide range in individuals with mental problems who are not alcoholic. It is a symptom of an illness, and the handling of the problem should be directed against the basic disease.

It has been my experience that these individuals have strong oral traits. As adults, they are fond of discussion, singing, and tobacco-smoking, and they have gastrointestinal complaints. While many of them are often men and women of some accomplishment, the majority display a rather typical lack of ambition or at least the absence of a concrete plan for living. Usually their jobs do not carry with them a great deal of responsibility. It is well known that many display latent homosexuality, which has been encouraged by an almost uniform type of mother whose emotional attitude was one of overindulgence, spoiling, and pampering. This leads to a feminine identification with a paucity of common masculine traits, such as aggression and direction of purpose. In addition, they prefer and are more at ease in a masculine type of environment. In their relationships with the opposite sex, these patients display poor adjustments, best seen in a weak heterosexual drive. They show an inability for maintaining normal relationships with socially accepted women.

Therapeutic approaches have been scientific in procedure. The religious approach or the Alcoholic Anonymous has some merit, and good results can be looked for in those who are essentially psychoneurotic. The schizophrenic patients are definitely a greater problem. Recently I had an opportunity to watch the "conditioned-reflex treatment" in a patient who for years had been refractory to institutional treatment and to religious and psychotherapeutic approach by competent Where the latter had completely psychiatrists. failed, the conditioned-reflex treatment succeeded in altering alcoholic habits and, apparently, has in some mysterious way given the patient some insight into his conflicts. Still more recently some good results of Alcoholics Anonymous have been seen. The great reservoir of chronic alcoholics is found in the courts.

Miller\* reviews the subject and stresses a threepoint program consisting of medical treatment, psychotherapy, and social reorientation and rehabilitation. His methods are quite ingenious.

In spite of all treatments, however, the most sensible approach is to obtain knowledge of the underlying psychopathology so that the psychiatrist may aid the patient in appreciating emotional insight. To quote Paul B. Brooks in his "Dr. Jones Says" column in the Health News: "But it's like a dog with a tin can tied to his tail; the faster he runs the more commotion there is to escape from. If the dog's got sense enough he'll stop when he comes to somebody he knows is his friend and let him untie the can."

<sup>\*</sup> Miller, M. M.: J.A.M.A. 120: 271 (Sept. 26) 1942.

Air encephalography was performed in 18 of the cases, usually when symptoms had been persistent for a considerable period of time. In 8 of these, definite pathologic findings were elicited, chiefly in the nature of ventricular distortion and dilatation or excessive collections of air in the subarachnoid spaces. In 3 cases, the injection of air was of marked therapeutic value. in approximately 45 per cent of the cases where air study was performed, positive findings were noted, and in these cases, this was the only objective evidence that could be found. Friedman, in a larger series of cases, has shown how the encephalogram may be the only means whereby organic changes can be shown in cases of so-called "traumatic neurosis."

Because of the recency of electroencephalography, only 6 of the patients had electroencephalograms performed, and in 2 of these positive findings of cerebral damage were noted. this is admittedly too small a number of cases to warrant any generalization, the noteworthy point, as with the air studies, is that in these 2 cases this was the only objective finding in the patients. Denis Williams, 10 in a series of 500 cases of head injury, found definitely abnormal electroencephalograms in approximately 50 per cent of chronic post-traumatic states, and "the abnormality persisted for many years after the injury." Marmor and Savitsky 11 have similarly reported recently positive electroencephalogram findings in 8 of 11 cases diagnosed as post concussion syndrome.

## Discussion

As a result of the above follow-up study, it would seem that more caution should be observed in rendering too optimistic a prognosis in cases of cerebral concussion. In round figures, only about 10 per cent were symptom-free in a month, and at the end of a year, about 30 per cent were still suffering from the usual triad of headache, dizzy spells, and nervous instability. In approximately 20 per cent of the cases, symptoms were still persistent after two years, and this figure was only slightly reduced after three years. About 15 per cent of the patients were still suffering from symptoms after three years, and in these cases the sequelae seemed permanent. Though at first glance these figures appear to make for a rather dismal prognosis, it must be borne in mind that a good many of the cases were seen only after the symptoms had already been persistent for a considerable period of time. The neurologist is not, as a rule, called in to see all cases of cerebral concussion, especially if the period of unconsciousness is minimal and the patient's progress seems to be satisfactory. Though this would tend to exclude a certain number of the less severe cases, yet a good many were seen by the author in the earliest stages, especially on the wards at Bellevue Hospital. The general impression of the author is that the persistent sequelae may be somewhat greater than the average for this reason, but only slightly so. Glaser and Shafer,12 in a follow-up study of 255 cases of brain trauma, observed that 46 per cent of the patients over 50 years of age continued to have subjective complaints from one and a half to five years, and even in patients under 50, such symptoms persisted in 23 per cent. In 31 per cent of their cases, headaches and dizziness persisted during the entire fivevear period. Their figures seem even worse prognostically than the author's, probably because of the fact that cases of skull fracture and focal brain lesions were included in their series. Yet only 32 per cent of all their cases showed any positive neurologic signs on examination, and. as these authors observed, symptoms were less likely to develop in patients suffering from depressed fractures than in those without fracture. If only this fact could be impressed on our friends in the legal profession, a great step forward would be made.

A similar study by Wechsler<sup>13</sup> on 100 consecutive cases of head injury, seen in practice, included about 25 per cent of patients with focal neurologic signs, yet persistent subjective complaints were present in 74 per cent of all cases. Though many of these were thought by Wechsler to be psychogenically motivated because of the the associated presence of litigation, in 28 per cent he felt convinced that a traumatic encephalopathy was present, even in the absence of positive neurologic signs. Russell,14 following up his series of head injuries, found 86 of 141 cases, or approximately 60 per cent, with persistent symptoms after six months, and this figure is all the more striking when one considers that in only 14 of these cases was there any question of pending compensation of litigation. It would seem, therefore, that the more one studies these cases, the more one is impressed with the substantial number of patients whose post-concussion symptoms are considerably prolonged. all tend to remember our favorable experiences more vividly and tend to overlook the less frequent, though substantial, number with persistent residuae.

Age, at time of injury, as repeatedly stressed by almost all observers, is of cardinal prognostic value. The younger the patient, the more hopeful the outlook, and the above figures only emphasize a fact already well appreciated. Patients over 40 years of age are twice as likely to have persistent sequelae as those under 30.

Another point worth stressing here is that

cards because of an impairment in concentration and difficulty in quick, accurate thinking. Whereas previously there had been a desire for reading, this was now lost, becoming secondary to the requisite mental effort. In short, in many cases, there had occurred a profound personality alteration which superficially resembled the functional complaints of the neurotic, yet neurotic symptoms had not been present prior to the head injury. No history of previous "nervous breakdown" was obtained. All patients had previously adjusted well to the customary economic, social, or marital stresses encountered in average existence.

"How long will these symptoms last?" The difficulty in giving the patient or the referring physician an accurate answer to this question merited further study.

In this series, headache was complained of in 62 per cent of the cases. It was often described as "bursting," or "hammering," and varied in location, though again in contrast to the neurotic, it was only rarely referred to as a "pressure on the top of my head." Sudden changes in the position of the head would often bring on a paroxysmal attack of severe headache and dizziness, occasionally with nausea. These headaches persisted in varying duration, from less than twentyfour hours, to well over three years and in 20 per cent of the cases were still present after three years (see Table 2). The minority (10 per

cent) of cases in which the headache lasted less than thirty days, occurred almost entirely in those younger individuals under 30 years of age, and there was an almost proportionate increase in the duration of the headache with each succeeding decade. With but few exceptions, the headaches persisting over two years were in patients over 40 years of age.

Dizziness was the second most prominent symptom complained of, and was present in 58 per cent of the cases. At times it was prolonged, and in 16 per cent of the cases it was still present after three years (see Table 3). As with headaches, the prognosis was very poor if the dizziness persisted longer than from one to two years,

very few patients recovering after two years. The dizzy spells in these patients must not be confused with true vertigo, which, fortunately, was rare in this series. Instead it was a giddiness usually produced by sudden change in position of the head, with an associated feeling of faintness. Similar symptoms are often seen after a severe illness, when the patient has been bedridden for some time, and first attempts to walk again. According to Rowbotham,2 these "momentary blackouts" are due to an instability of the cerebral circulation consequent upon injury to its vasomotor apparatus. Because of this momentary ischemia of the brain, a feeling of giddiness is produced in a manner similar to the mechanism of syncope. This is an attractive theory, but it must be borne in mind that in many cases of cerebral concussion, actual damage has also occurred to the vestibular mechanisms. Brunner,3 Linthicum and Rand,4 and most recently, Zacks,5 have emphasized the frequency of labyrinthine damage in these cases, and unless vestibular tests are routinely performed, such evidence of impairment is not elicited by the usual neurologic examination. According to these observers, the head injury is often productive of degenerative changes in the cochlear nuclei, with localized areas of altered circulation due to the altered irritability of vasodilators and vasoconstrictors. The traumatic paralysis of the vasoconstrictors is probably the result of damage to the brain stem, a thesis strongly advocated by Denny-Brown and Russell,6 in their experimental work to be described below. Further support to this theory of a primary vasomotor origin of symptoms has been afforded by the pathologic studies of Helfand,7 in a series of 22 cases of brain trauma, and recently by Malones who, by using prostigmine, a vasodilator, was able to afford substantial relief to many of these patients with the symptoms of "postconcussion syndrome."

"Nervous instability," so frequently found in this series, has already been described above. As with the other symptoms mentioned, its duration was quite often prolonged (see Table 4).

TABLE 4.—Duration of "Nervous" Symptoms

INDED 4: 2	180

It must again be emphasized that in these cases, no litigation or compensation motive was present, yet many of the patients had unfortunately been labeled "neurotic," chiefly because of the prolonged duration of symptoms. No case of post-traumatic psychosis was encountered. fixed when struck, for when this was done, a crushing injury with several cerebral contusion was produced, quite different from that obtained in concussion. When the head was allowed to go forward with the blow, a mechanism more nearly similar to that of the usual head injury, typical cerebral concussion was produced. The essential factor seemed to be a sudden change in speed of the brain within the skull, and it was calculated that the requisite acceleration necessary was from 0 to 23 feet per second. further noted, as a result of these head injuries, a disorder of bulbar function, with stimulation of the vasomotor centers in the medulla, and a rapid vasoconstriction, comparable to a sudden asphyxia. Though a rise in intracranial pressure was occasionally present, it was not an essential feature of the concussion. It was their feeling that loss of consciousness is associated with microscopic changes in the nerve cells of the brain, resulting from physical acceleration of these cells. These findings would help us understand the observations of Cloward, since the speed at which the projectiles were traveling was so great that the head was struck, perforated, and penetrated before the brain as a whole had time to be set into motion, and it is interesting to note that, in his cases, there was an absence of linear fractures of the skull around the point of entrance of the projectile, which, as Cloward comments, is "further evidence of the high speed the missiles were traveling." Lastly, it should be emphasized that such an explanation is true in other than high-speed bullet or shrapnel wounds. Earl Walker<sup>21</sup> has reported the case of a man who, while lying under an auto, had the car jack slip, crushing his head between the car and the ground and producing an extensive fracture of the skull, yet with no loss of consciousness whatsoever. Here the head, because of the support of the ground, was not subjected to the acceleration resulting in most head injuries, since it was in a fixed position when struck.

It would seem high time, therefore, that neurologists placed less weight on absence of unconsciousness in their estimation of the severity of original head trauma and brain damage. Like the Wassermann reaction of the blood. positive findings are usually conclusive but negative results not exclusive.

In conclusion, a few words as to similar residual symptoms in allied cerebral lesions may not be out of place. The author has recently seen 5 cases of carbon monoxide poisoning, all asphyxiated at the same time by escaping fumes from a leaking gasoline engine. All were rendered unconscious at the time of the accident, and despite the lapse of a year, persistent symptoms of headaches, nausca, dizziness, and difficulty in con-

centration were present in all these 5 men. Prolonged residuae, after such acute poisoning, have been accepted by authorities on this subject, such as Drinker,22 Henderson and Gillespie,23 and others, and it is recognized that, in these cases, the brain cells have been damaged because of the resulting anoxemia, secondary to carbon monoxide's affinity for the hemoglobin of the blood. Petechial hemorrhages in the brain are often noted in such cases, and similar cerebral lesions have been described as a result of electrocution and recently in cases of blast concussion in England (Fulton<sup>24</sup>), as well as in immersion blast injuries by Hamlin.25 The striking resemblance of symptoms in these definitely "organic" lesions to those of the postconcussion syndrome described above, cannot be ignored in the evaluation of this problem.

## Summary

1. A follow-up study of 100 cases of cerebral concussion has been made. No cases of more severe brain injury, such as skull fracture or focal cerebral contusion, were included. Cases where litigation or compensation factors were present or where a strong psychogenic element seemed to be a part of the picture were likewise eliminated from the study.

2. The residual symptoms have been analyzed as to duration. Headaches, dizziness, and various symptoms of nervous instability, persisted in approximately 1/3 of the cases for more than one year. In about 15 per cent of all cases, symptoms were still present after three years and appeared permanent.

3. In the duration of symptoms, the outstanding importance of the age of the patient is stressed. The prognosis seems twice as favorable in patients under 30 as in those over 40 years of age.

4. Loss of consciousness was not present in approximately 20 per cent of the cases, yet the persistence and severity of symptoms in this group was no less than in those where unconsciousness had been present.

5. Air studies and the electroencephalograms were of definite help in a considerable number of cases, in pointing out definite cerebral lesions despite a normal neurologic examination. The importance of these procedures in the evaluation of these cases is stressed. One cannot escape the conclusion that as our diagnostic technic and instruments of precision become more refined, more and more of these cases, hitherto labeled neurotic, can be proved to have important brain alterations. The medicolegal value of these data cannot be overlooked.

6. More recent work on the subject of cerebral concussion is reviewed and the similarity of care must be taken lest the above figures on persistent symptoms be interpreted as total inability to return to work. Many of the patients, though still complaining of residual symptoms, were back on their jobs, doing their housework, etc. It is quite conceivable that, had the question of compensation complicated the picture in these cases, the results would have been even more unfavorable. Though efficiency may have been impaired, economic necessity kept at their tasks many patients who, had this incentive been absent because of regular compensation benefits, might have succumbed to a life of complaining and neurotic invalidism.

Air encephalography and electroencephalography proved of great value in establishing the organicity of the complaints in a substantial number of cases in which this procedure was performed. The value of these sources of additional information cannot be denied, and it is the author's distinct impression that with the increasing knowledge of the electroencephalograms, and its wider application in head injuries, this will become a standard procedure in these cases. From the medicolegal standpoint, it is often decisive, as it may be the only "objective" data supporting the genuineness of the patient's complaints. The high percentage of positive findings in cases of post-traumatic concussion symptoms has already been mentioned (Williams, 10 Marmor and Savitsky<sup>11</sup>).

Loss of consciousness is important when present and of long duration, but its absence does not exclude severe brain damage. In 12 cases in this series there was no loss of consciousness whatsoever, and in another 8 only momentary "stunning," a total of 20 per cent of all cases. No lesser severity of postconcussion symptoms in this group than in the average of the series was noted. This fact has been corroborated repeatedly by various observers. Russell,14 in his study of 200 cases of head injury with severe post-traumatic sequelae, commented that, in many of these cases, "unconsciousness was present for a few moments only, yet some of the patients with the longest period of unconsciousness had practically no residual symptoms." Strauss and Savitsky<sup>15</sup> were also impressed with the frequent lack of association between duration of unconsciousness and severity, or persistence, of symptoms. They aptly point out that we accept the rupture of relatively large intracranial vessels, such as occur in subdural hematoma, or epidural hemorrhage, with only the history of a dazed state and, unquestionably, such cases have been reported. Traumatic epilepsy following head injury without original loss of consciousness has been reported by Hughlings Jackson<sup>16</sup> and Josephowitsch.17 Furthermore, it has long

been recognized that, following head traums, a patient may go through a fugue state during which time, though consciousness is maintained. there is a period of amnesia for the events occurring during this time interval. The well-publicized experience of Eugene Tunney,18 describing a personal experience of cerebral concussion with a long episode of amnesia, though consciousness was intact, is worth rereading, and similar experiences on the part of prize fighters are common knowledge. Foster Kennedy<sup>19</sup> has described the case of an officer in the last war, who suddenly went blind, yet denied that he had been hit; all he knew was "that daylight had been replaced by complete blackness." At the casualty clearing station a tiny, crescent-shaped abrasion was found above the hairline on the temple, and x-ray examination revealed a small sliver of steel in the optic chiasm.

The intensely interesting experiences at Pearl Harbor have recently been most dramatically recorded by Cloward.20 As the result of the bombing of Hawaii on December 7, 1941, many brain injuries were encountered secondary to shrapnel penetration through the skull. Large jagged pieces of metal, traveling at high speed, had ripped great irregular holes in the tissues of the head and sunk into the brain. In many of the cases the fractured bone fragments were carried into the brain, lacerating cortical vessels and brain substance over a wide area. Yet "few of the patients with penetrating wounds of the brain were brought to the receiving station in The majority of them an unconscious state. had not even been unconscious, but were able to recall everything that had transpired from the time they were hit until they arrived at the hospital. This was a most surprising fact to the doctors who saw these cases. Patients with large gaping wounds in the frontal areas, with considerable quantities of cerebral tissue oozing from the wounds, were found to be conscious, cooperative, rational, and able to give their identification."

Many other recorded experiences of similar type could be quoted. Unfortunately, though the medical literature abounds with reports of cases of brain injury without loss of consciousness, this experience is too frequently ignored in assessing the severity of the brain damage. Without going into a long discussion as to the pathogenesis or histologic alterations in these cases, it would seem that the crucial point in the production of the concussion syndrome is the acceleration, positive or negative, of the brain at the time of the head injury. This would seem to be definitely proved by the outstanding recent work of Denny-Brown and Russell.<sup>6</sup> In their experimental animals, they did not allow the head to remain

fixed when struck, for when this was done, a crushing injury with several cerebral contusion was produced, quite different from that obtained in concussion. When the head was allowed to go forward with the blow, a mechanism more nearly similar to that of the usual head injury, typical cerebral concussion was produced. The essential factor seemed to be a sudden change in speed of the brain within the skull, and it was calculated that the requisite acceleration necessary was from 0 to 23 feet per second. further noted, as a result of these head injuries, a disorder of bulbar function, with stimulation of the vasomotor centers in the medulla, and a rapid vasoconstriction, comparable to a sudden asphyxia. Though a rise in intracranial pressure was occasionally present, it was not an essential feature of the concussion. It was their feeling that loss of consciousness is associated with microscopic changes in the nerve cells of the brain, resulting from physical acceleration of these cells. These findings would help us understand the observations of Cloward, since the speed at which the projectiles were traveling was so great that the head was struck, perforated, and penetrated before the brain as a whole had time to be set into motion, and it is interesting to note that, in his cases, there was an absence of linear fractures of the skull around the point of entrance of the projectile, which, as Cloward comments, is "further evidence of the high speed the missiles were traveling." Lastly, it should be emphasized that such an explanation is true in other than high-speed bullet or shrapnel wounds. Earl Walker<sup>21</sup> has reported the case of a man who, while lying under an auto, had the car jack slip, crushing his head between the car and the ground and producing an extensive fracture of the skull, yet with no loss of consciousness whatsoever. Here the head, because of the support of the ground, was not subjected to the acceleration resulting in most head injuries, since it was in a fixed position when struck.

It would seem high time, therefore, that neurologists placed less weight on absence of unconsciousness in their estimation of the severity of original head trauma and brain damage. Like the Wassermann reaction of the blood. positive findings are usually conclusive but negative results not exclusive.

In conclusion, a few words as to similar residual symptoms in allied cerebral lesions may not be out of place. The author has recently seen 5 cases of carbon monoxide poisoning, all asphyxiated at the same time by escaping fumes from a leaking gasoline engine. All were rendered unconscious at the time of the accident, and despite the lapse of a year, persistent symptoms of headaches, nausea, dizziness, and difficulty in con-

centration were present in all these 5 men. longed residuae, after such acute poisoning, have been accepted by authorities on this subject, such as Drinker,22 Henderson and Gillespie,23 and others, and it is recognized that, in these cases, the brain cells have been damaged because of the resulting anoxemia, secondary to carbon monoxide's affinity for the hemoglobin of the blood. #### Discussion

Dr. G. Kirby Collier, Rochester, New York-Dr. Denker has most carefully analyzed a series of 100 concussion cases, excluding the more severe brain trauma and those showing definite organic neurologic residuals. He tells us that he has further eliminated from this study those cases in which "a strong psychogenic element seemed to be a part of the picture" and that no litigation or compensation motive was present. The symptom picture presented by him is similar to that seen by all of usheadache, dizziness, lack of concentration, emotional instability, insomnia, etc. Most significant to me is his statement that in approximately 50 per cent of those who had an air encephalography done, definite abnormal findings, such as subarachnoid air, distortion or dilatation of ventricles was noted. Again, in his reference to the age incidence, Dr. Denker makes a statement which I feel is quite significant, in that the patient over 40 years of age is twice as liable to have persistent symptoms as those under 30. We cannot escape the encephalographic findings, even though the series is small, and they were done after a considerable lapse of time. Does this not imply that any disturbance of the brain in its bony box must be followed by some damage—a generalized swelling or edema, followed later by a dehydration, and later still by a cortical atrophy of some degree? In that group under 30 years of age, reparative changes would be more active than in the older group. Whatever the pathologic changes are they are of varying degree Without reviewing the other findings in the very informative paper, should we not consider always the psychogenic background of our patient as being a most important factor in prolonging symptoms in these concussion cases?

In our history taking, we often find life situations which the patient is unwilling to discuss. Many times these are situational factors in the immediate past and at times have some relationship to the accident.

#### CONTRACEPTIVE PREPARATIONS ACCEPTED

The first list of contraceptive preparations and devices accepted by the Council on Pharmacy and Chemistry of the American Medical Association for inclusion in its publication, New and Nonofficial Remedies, is published in the December 18 issue of the Journal of the Association.

In its announcement the Council says that "At its annual meeting in 1942 the Council on Pharmacy and Chemistry declared contraceptives eligible for consideration on the same basis as therapeutic agents.

Prior to this time the Council's consideration of the contraceptive problem had consisted in sponsoring with the Council on Physical Therapy (of the Association) occasional status reports. To aid the Association) occasional status reports. Council in its considerations, an Advisory Committee consisting of outstanding authorities in this

field was formed and it prepared a set of criteria 50 that contraceptive agents might be evaluated consistently and fairly . . . . The Council on Pharmacy and Chemistry has received the status of appliances submitted by two firms but voted to refer all other submissions of appliances to the Council on Physical Therapy. Thus there follows on these pages a description of certain physical devices which received early consideration by the Council on Pharmacy and Chemistry.

"The Council has also authorized publication (in this issue of the Journal) of a status report by Dr. Robert L. Dickinson, of New York, a statement of actions and uses for New and Nonofficial Remedies, and criteria on which such contraceptive agents have been examined. As pointed out, these criteria

may be changed as experience grows.

## SIXTEEN YEARS' EXPERIENCE WITH PLACENTA PRAEVIA EMPHASIZ-ING CONSERVATIVE THERAPY

WARD L. EKAS, M.D., Rochester, New York

PLACENTA praevia is generally considered the most common as well as the most serious cause of antepartum hemorrhage. Bleeding of a greater or less amount is inevitable because of the anatomic relationship of the placenta to the lower uterine segment, as sooner or later there is a stretching of this segment of the uterus. The first bleeding may occur early in the pregnancy, and be diagnosed as a threatened abortion, and about 10 per cent of placenta praevias are said to give such symptoms. When the bleeding occurs later in the pregnancy it may be slight or exsanguinating. Fortunately, the former is the more common. Since painless bleeding or hemorrhage is the cardinal symptom of this condition, any patient who has painless bleeding should be examined promptly to establish a diagnosis.

The diagnosis is entirely dependent upon a physical examination. The hemorrhage is only a symptom of some abnormal condition. One must differentiate premature separation of a normally implanted placenta, polyps, cervical or vaginal erosions, carcinoma of the cervix or vagina, vasa praevia, and at times vaginal injuries. Abnormal presentations of the fetus, failure of the presenting part to engage, or the placental bruit being best heard immediately above the symphysis pubis may indicate a praevia. If on vaginal examination there is unusual cyanosis of the mucosa, marked pulsations in and about the fornices, and the cervix itself is unusually soft and possibly somewhat dilated, the suspicion is further increased. when the examining finger is passed up into the cervix, a soft, spongy mass is felt between the finger and the presenting part or the edge of the placenta, there can be no mistake in the diagnosis.

The x-ray has been used with success by some to diagnose placenta praevia, but in our clinic the results have not been too reliable. Cystograms, or pictures taken so as to differentiate the placenta and uterine wall, are the usual tech-

The prognosis, for mother and baby, is affected by several factors: the amount of hemorrhage before, during, or after delivery, the duration of

the pregnancy, the presence or absence of infection, the variety of placenta praevia, the amount of placental separation, the amount of dilatation as well as the consistency of the cervix, injuries to the birth canal, the method of treatment, some other complications, and perhaps most of all by the ability of the obstetrician and the available facilities, such as plasma, blood, and assistants. The maternal mortality is said to vary from 1 to 19 per cent, while the fetal mortality varies from 10 to 80 per cent.

In the treatment of placenta praevia the first prerequisite is that the hemorrhage be controlled as soon as possible. The second is that the procedure selected shall contribute to the termination of the pregnancy and labor with as great safety as possible to the mother and to the child, if it is living and viable. Third, scrupulous attention to technic to prevent infection must be observed.

Every case of placenta praevia should be hospitalized, if it is at all possible. Vaginal examinations should never be done until preparations have been completed to control bleeding, and blood and/or plasma is immediately available; otherwise a fatal hemorrhage may occur-The prospective donors must be kept at hand until danger of hemorrhage is past.

The methods of treatment are of two types: first, those which aim at delivery through the birth canal, and, second, those which aim at delivery by some type of cesarean section. In recent years there has been a decided trend toward the use of cesarean section in the treatment of this condition. In one series, cesarean section has been used for all types of placenta

Of the obstetric, or so-called conservative measures, several are used. The simplest, perhaps, is the artificial rupture of the membranes, and unless the patient is in labor, the application of a tight abdominal binder to hold the presenting part against the placental edge to control the bleeding. This method is of particular value in the marginal variety of placenta praevia, when the head is fairly well into the pelvis. The outcome is usually satisfactory for mother and child.

A second procedure is the Braxton-Hicks bipolar version, but this requires considerable obstetric skill and can only be used when the cervix will admit two fingers. It has been recommended for use in the home when other means

Read at the Annual Meeting of the Medical Society of the

State of New York, Buffalo, May 4, 1943.
From the Department of Obstetrics and Gynecology, University of Rochester School of Medicine and Dentistry. Rochester, New York.

are not available to control hemorrhage, but its use is questioned, because a person with limited obstetric ability is supposed to carry out a maneuver requiring skill above the average.

A third procedure is the use of the Willett's forceps. Although it has not been used in our clinic, it would seem to have a definite place in the armamentarium of an obstetrician. It is a modified volsella forceps which can be clamped to the fetal scalp after the membranes have been ruptured. It can be best used when the fetus is dead, but is also usable on viable fetuses. Care should be taken not to attach it over a fontanelle or suture line. A weight of one or two pounds is fastened to the other end of the forceps. This forceps would seem to have particular merit in the treatment of the marginal or partial varieties of placenta praevia when they must be handled in the home, since no great skill of manipulation is exercised in its use.

The fourth procedure is the use of the Voorhees' bag, which is, of course, primarily a hospital procedure. As a rule, the patient should be anesthetized. The patient is examined vaginally to determine the presence of a placenta praevia. The membranes are ruptured, as the bag should always be placed intra-ovular, for only if it is so placed will the bag compress the placental edge against the cervix and control bleeding as well as stimulate uterine contractions to aid in dilating the cervix. Extra-ovular insertion of the bag is not mechanically sound, as it in no way serves to control bleeding, and it may cause further separation of the placenta with the resultant formation of a concealed hemorrhage. The bag used should be large enough to insure complete dilatation of the cervix when it comes out. When the bag is rolled up, it can easily be inserted through a 2 to 3 cmcervix, with the forceps used to introduce it. By knowing its capacity beforehand, it can be filled without putting too much tension on it, and possibly having it burst. There is no need to place packing around the cervix or in the vagina. After the stem is securely tied, and perhaps clamped, the patient is placed in her bed and a weight of 1 or 2 pounds is attached to the stem, by means of a tape, and hung over the foot of the bed. The traction insures continuous pressure to control hemorrhage as well as to stimulate pains.

The patient, as a rule, starts in labor in a short time and her progress must be closely followed so that delivery can be effected promptly after the bag is expelled through the cervix. It is even better to have the patient prepared for delivery just before the passage of the bag through the cervix, for if this is done babies can at times be saved. The placenta may sepa-

rate more at this time and cause asphyxiation of the baby, or increase the amount of asphyxiation of a baby already in difficulty. The possibility of hemorrhage as a result of removal of pressure in releasing of the bag may be lessened if the presenting part does not promptly drop into the cervical canal. The bag invariably displaces the presenting part, but in the majority of cases it descends again and controls the hemorrhage. The cord may prolapse at this time too. For the above reasons, the entire operating room personnel must be immediately available when the bag is expelled from the cervix. Delivery is conducted in the most conservative manner. If the head comes down and the bleeding is minimal, spontaneous delivery is awaited, or forceps applied if necessary. If it is a breech presentation, an extraction is done. If there is a persistent abnormal presentation, prolapsed cord, or profuse bleeding, labor is terminated immediately by internal version and extraction. The third stage of labor is conducted as circumstances indicate.

The advantages of the use of the hydrostatic or Voorhees' bag are: (1) The bag can be used in all cases, (2) the bag controls hemorrhage and stimulates labor pains, thereby aiding in the dilatation of the cervix so that delivery can be completed without undue delay, (3) less risk is incurred by the mother than by surgical methods, (4) less technical skill is required so that a wider use can be made of this method, (5) the presence of infection in no way contraindicates its use, and (6) the rate of maternal mortality will be lower.

The disadvantages of the Voorhees' bag are:
(1) Some babies are lost by asphyxia, prolapse of the cord, or injuries in obstetric procedures aiming at delivery; some of these would die from prematurity, as a large percentage of them are premature. (2) The rubber in the bags deteriorates rapidly, necessitating frequent inspection and replacement. (3) Its use is definitely limited to hospital practice. (4) There is added risk of infection.

As stated previously, cesarean section is being done more and more for placenta praevia. The type of operation used depends upon the operator and the circumstances of the case. Cesarean section has a very definite place in the treatment of this condition, but its use is limited to those who are surgically trained, and the surgical ability further determines the type of section done. Any surgeon can do a classical cesarean section, but it requires special training to do one of the more specialized types of section, and these must be used if cesarean is to be used as a treatment for placenta praevia. Cesarean section may be done on a patient in good condition who

has a central placenta praevia, and occasionally on a patient with a partial placenta praevia and a long, closed cervix, providing she is not infected and the sterile examination has been the only vaginal manipulation. The child should be viable and apparently normal.

Seeley's states five contraindications to cesarean section: (1) shock from blood loss, (2) a cervix dilated 4 or more cm. in a patient in active labor, (3) vaginal tamponade previously done, (4) previous attempts at delivery from below, and (5) doubtful sepsis from repeated vaginal examinations.

Seven years ago, I reported a series of 36 cases of placenta praevia at the State Society Meeting. Since then our total number of cases has increased to 86. This demonstrates an incidence of 1 in 167, or 86 in 14,386 cases. In 66 cases, or 76.6 per cent, the Voorhees' bag was inserted to control bleeding and induce labor. In only 4 cases a cesarean section was done. Four cases had had placenta praevia in a previous pregnancy, and one a premature separation. Eleven cases were in primiparas. Thirty-six, or 41.8 per cent, had spontaneous deliveries and 50, or 58.2 per cent, had operative deliveries. Central placenta praevia occurred six times, partial twenty times, marginal fifty-nine times, and one case was unclassified. Table 1 shows the type of placenta praevia and the treatment.

Manual removal of a part or all of the placenta was necessary in 18 cases, 7 of which were full term. In only one case was it necessary to tamponade the uterus to control hemorrhage, and this was a case of five months' duration. One or 2 cc. of pituitrin were given intramuscularly, routinely, after the third stage of labor, and ergot was given when necessary. Prolapse of the cord was encountered three times and 2 of

the babies were delivered alive by version and extraction. In one case at term the baby died. Two cases had cervical lacerations that required suturing. Sixty-nine were vertex presentations, 15 breech, and 2 transverse.

Age Incidence.—Twenty-four patients were between 19 and 25 years of age, 21 between 26 and 30, 23 between 31 and 35, 15 between 36 and 40, and 3 over 41.

Period of Gestation.—Twenty-four cases were from five to seven months, 29 from seven to eight months, and 33 from eight to nine months.

Duration of Bleeding.—Of the 86 patients, 46 had had bleeding for less than twenty-four hours before admission, 13 from two to seven days, 14 from one to four weeks, and 13 for a longer time than four weeks. Fourteen patients, or 16 per cent, were treated for threatened abortion in early pregnancy. A patient who has bleeding early in pregnancy may be the placenta praevia case later.

The labors, as a rule, were short. Fifty-seven patients had less than ten-hour labors, and 26 of these lasted less than five hours. Seventeen patients had labors longer than fifteen hours. Three labors were quite prolonged. One fifty-two-hour labor and another of sixty-eight hours occurred in primiparas, both of whom delivered living term babies, and the third, a sixty-hour labor, was in a para I who was delivered of a 1,660-Gm. child, who later died.

The maternal morbidity rate was high. Thirty-four, or 40 per cent, of the patients had a febrile puerperium. Six were only one-day fevers. One was possibly due to a respiratory infection and another to pyelitis. One had bronchopneumonia. Twenty-four had intrauterine infections. Three patients developed a thrombophlebitis, two after discharge from the

hospital. One of these died, as noted later. See Table 2.

There were two maternal deaths in the series, or a mortality of 2.32 per cent. The following is a summary of the histories of these cases.

Case 1.-The first woman was a 30-year-old gravida I at term. There had been bleeding for three days and the patient was obviously infected on admission. A marginal praevia was diagnosed and a Voorhees' bag inserted. She was delivered of a living full-term child, by version and extraction after a sixty-eight-hour labor. Manual removal of the placenta was done. It was estimated that the blood loss at delivery was not more than 300 cc. She died of a hemolytic streptococcus septicemia. Six transfusions were given.

Case 2.—The second was a 20-year-old primipara who was six months pregnant. She was admitted the day bleeding occurred. The fetal heartbeat was never heard. A marginal placenta praevia was found and a Voorhees' bag inserted. Delivery was spontaneous, with a blood loss of 500 cc. Her postpartum course was uneventful and afebrile. A transfusion of 500 cc. of citrated blood was given. was discharged from the hospital on the eleventh Four days later, she was readmitted because of fever and chest pain. Pelvic examination was negative. The diagnosis rested between pneumonia and a pulmonary infarct. She did well for eleven days and then had a pulmonary embolus and died in thirty minutes. No autopsy was done.

Fetal Mortality .- Sixty babies, or 70 per cent, were alive when born. One full-term child died of congenital heart disease, another after prolapse of the cord and a difficult delivery. Four premature and 14 immature babies died of prematurity. One premature baby died from atelectasis.

Babies weighing less than 1,500 Gm. are called immature, those between 1,500 and 2,500 Gm. premature, and those 2,500 Gm. and over full term.

#### TABLE 3 .- FETAL MORTALITY

60 babies, or 70 per cent, were alive when born.
23 full term. One died of congenital heart disease.

One died after prolapsed cord and difficult de-livery.

21 premature. Four died of prematurity. One died of atelectasis.

16 immature. Fourteen died of prematurity.

27 babies, or 30 per cent, were stillborn.
8 full term. Five were dead on admission. There were three intrapartum deaths. One of these

heard only on admission.

emature. Three were dead on admission. There 9 premature. were six intrapartum deaths.

10 immature. Six were dead on admission.

48 babies were dead on admission or died, giving an un-corrected mortality of 55.8 per cent.

There was one pair of premature twins.

Twenty-seven babies were stillborn; of these 8 were full term, 9 premature, and 10 immature. Nine of the stillborn deaths occurred intrapartum; three of the babies were full term, and 6 premature. Thirty-one babies were full term, 29 premature, and 26 immature. The uncorrected fetal mortality rate was 48, or 55.8 per cent. Perhaps 3 full-term and 6 premature babies could have been saved by cesarean section. See Table 3.

Transfusions.-From one to six transfusions were given in 33 cases; 500 to 600 cc. of blood were given at a time.

Every case of placenta praevia should be grouped and matched as soon as possible after admission to the hospital. This should be done before any operative or even diagnostic procedure is done. The prospective donors should be kept at hand so that they are immediately available. Transfusions should be given to combat shock and to replace blood loss. Not infrequently, more than one transfusion may be necessary. Since plasma is available even to the country practitioner treating a patient in the home, it can save the lives of patients when a transfusion could not be given immediately. The lifesaving value of transfusions of whole blood and plasma cannot be too strongly emphasized.

The first danger to the mother is hemorrhage. Early appreciation of the importance of the first bleeding in the latter half of pregnancy cannot be stressed too strongly. In the series reported seven years ago 50 per cent had had bleeding for longer than one week before consulting a doctor, and 331/2 per cent for longer than four weeks, but in the total series these figures were 31 per cent and 25 per cent. Also in the first series of cases, 331/3 per cent entered the hospital with a history of bleeding less than twenty-four hours, and in the whole series the figure was 53 per cent. I should like to believe that this shows the effect of our teaching of prenatal care. If these cases are seen early, not

only is less blood lost, but the chance of infection is less.

In this series 40 per cent of the patients had a febrile puerperium, and 30 per cent had puerperal infections. This also shows a lowering from the figures in the first series from 50 per cent and 33½ per cent, respectively. Both patients in this series died as a result of infection.

The above figures indicate that infection is to be feared as much as hemorrhage and that vaginal examinations, vaginal tamponade, if done, and operative procedures should be carried out with the strictest aseptic technic. With use of the sulfa drugs many infections can be cured and many lives saved.

Fetal mortality is not dependent so much upon the method of treatment, for many of the babies are premature or immature and will die

of prematurity.

In this series of cases 36 per cent of the babies were classified as full term and 30 per cent as immature. Asphyxiation from separation of the placenta is a second factor in fetal mortality. At least 14 per cent of the babies were dead on admission. Nine babies, whom cesarean section might have saved, were lost by intrapartum deaths, but of course not all cesarean section babies live.

The following is offered as a procedure in treating a case diagnosed as placenta praevia.

- 1. Take the patient to the hospital, in an ambulance if possible. Do not insert a vaginal pack, for it may compromise the treatment later.
- 2. Group and match the blood of the patient with compatible donors and keep them at hand. Have plasma ready.
- 3. Have the operating room set up for a vaginal procedure to control hemorrhage and/or to do a cesarean section.
- 4. Do a careful vaginal examination after a thorough clean-up technic. Determine the variety of placenta praevia present.
- 5. If the patient is in labor and the presenting part is fairly well into the pelvis, a simple rupture of the membranes and the application of a tight abdominal binder will often suffice to control hemorrhage in the marginal and partial varieties of placenta praevia.
- 6. If the patient is not in labor and a marginal or partial variety of placenta praevia is present, rupture the membranes and insert a Voorhees' bag of sufficient size to fully dilate the cervix when it is expelled. The size of the bag used will depend upon the age of the fetus. If a central placenta praevia is present and the child is dead or immature, an opening may be made in the placenta and a bag introduced. In selected cases, when the fetus is immature or

dead, a Willett's forceps may be used. Attach a weight to the bag or forceps.

- 7. Watch the patient carefully and when the bag comes through the cervix, or preferably just before, place her again on the delivery table and effect delivery by the method that seems indicated. This may be spontaneously, by breech extraction, forceps, or version and extraction.
- 8. Watch for hemorrhage during the third stage of labor and manually remove the placenta if bleeding is profuse.
- 9. Give 1 cc. of pituitrin intramuscularly, before or after the placenta is expressed, and 1 cc. of ergotrate intravenously after expression of the placenta. Uterine tamponade is rarely necessary if the uterus is carefully watched.
- 10. For the case that would seem best treated by cesarean section, operation may be performed immediately after vaginal examination.
- 11. Give plasma and/or transfusions as indicated, before the examination, during the labor, delivery, or operation, and after delivery. Give a sufficient amount to replace blood loss. Carry out measures to combat shock. Glucose and saline may be given, too, as needed.

Watchful expectancy has no place in the treatment of placenta praevia. As soon as diagnosis is made, proceed with some method of treatment. Waiting may spell disaster.

Vaginal tamponade should rarely, if ever, be used, for it always introduces the possibility of infection, and it is doubtful if it ever serves the purpose for which it is intended.

Accouchement force, meaning "forceful dilatation of the cervix and delivery of the child," has no place in the treatment of placenta praevia. The cervix is merely lacerated or torn, and this means more hemorrhage and another avenue for infection.

#### Summary and Conclusions

- 1. A series of 86 cases of placenta praevia is presented.
- 2. Of these, 95.3 per cent were treated by conservative measures.
- 3. The Voorhees' bag was used in 76.6 per cent.
- 4. The maternal morbidity was 40 per cent, and the mortality 2.3 per cent.
- The uncorrected fetal mortality was 55.8 per cent.
- 6. Two factors, prematurity and asphyxia, keep the fetal mortality high.
- 7. Not enough importance is attached to the initial hemorrhage in the latter half of pregnancy.
  - 8. Transfusions of whole blood and/or

plasma in amounts sufficient to replace blood loss will save many lives.

- Infection should be feared as much as hemorrhage in treating placenta praevia.
- 10. Placenta praevia should be treated by conservative measures in the large majority of

cases, and cesarean section should be used in the small well-selected group.

## SAFEGUARDS NEEDED IN ESTABLISHING INTENSIVE TREATMENT OF SYPHILIS

An indication of the safeguards necessary in establishing the value of the intensive method of treatment of the venereal diseases is contained in a preliminary report on the activities of the Chicago Intensive Treatment Center, published in the Intensive Treatment Center, published in the November 27 issue of the Journal of the American Medical Association. The report is presented by Herman N. Bundesen, M.D., Theodore J. Bauer, M.D., and H. Worley Kendell, M.D., Chicago, with the collaboration of R. M. Craig, M.D., G. X. Schwemlein, M.D., E. C. Sittler, M. F. Steves, M.D., E. A. Strákosch, M.D., Ph.D.; A. A. Rodriquez, M.D., and H. C. S. Aron, M.D., Ph.D. The Chicago Intensive Treatment Center is operated under grants received from the Federal

operated under grants received from the Federal Works Agency, the U.S. Public Health Service, the State of Illinois, and the Chicago City Council. It was dedicated on November 29, 1942, as an added facility in the Venereal Disease Control Program of the Chicago Health Department. As a wartime emergency activity, the primary objective of the Center is to control effectively, and as quickly and safely as possible, the spread of venereal diseases by making noninfective those who spread these diseases.

Three methods of intensive treatment for early syphilis are being employed at the Center—two comparative and one noncomparative method. The two comparative methods are: modified Simpson, Kendell, Rose (artificial fever in air-conditioned cabinet plus arsenobismuth therapy), referred to at the Center as fever-chemotherapy, and the modified Schoch-Alexander method (multiple, short term arsenobismuth therapy), called intensive chemotherapy at the Center. The noncomparative chemotherapy at the Center. The noncomparative method is the modified Eagle-Hogan method (multiple syringe, long term arsenobismuth therapy), called long term intensive chemotherapy at the Center.

The average stay is seven days for patients in the fever-chemotherapy section and fourteen days in the intensive chemotherapy section. The two methods are being compared to determine whether

intensive chemotherapy, or one of its modifications may furnish an intensive arsenobismuth treatment to be given safely without the necessity for the elaborate equipment and highly trained personnel needed in fever-chemotherapy. Only those patients rejected for the two comparative methods are given long term intensive chemotherapy.

Patients admitted to the Center are given an extensive physical examination before treatment is started. The authors of the report say that "In our experience, intensive treatment is contraindicated in early active tuberculosis and certain forms of cardiovascular disease.

From November 10, 1942, through October 8, 1943, 931 patients were given fever-chemotherapy for syphilis. Two cases—the thirteenth and sixty-ninth—terminated fatally. After the first death the maximum dosage of mapharsen was reduced.

Following the second death, only those patients were allowed to receive either of the comparative treatments who were found to be free of active tuberculosis. Since the second death, 862 have been treated consecutively with no fatality or serious reactions. After the deaths improvements also were made in various phases of the fever treatment,

In a series of 488 patients, the number of failures has been 1.6 per cent (2 serologic and 6 clinical

Three hundred and ninety patients were treated with intensive chemotherapy, 172 receiving 1,200 mg. of mapharsen within ten days; 5.8 per cent failures were noted. The method was discontinued since reactions severe enough to stop treatment were encountered in 11.9 per cent of the cases treated. A modification was then adopted whereby all the mapharsen was given within seven days. The observation period of this group of patients is too short to allow any conclusion. Of 81 patients treated with long town intended. treated with long term intensive chemotherapy, 52 have thus far become serologically negative and one patient developed serologic relapse. There have been no clinical relapses to date.

# ITALIAN MOSQUITOS HUNTED IN WAR AGAINST MALARIA

The Eighth Army is being followed through the swamps of southern Italy by a man under government orders to capture several hundred malarial mosquitos of three varieties.

When the Japanese occupied Java they obtained 93 per cent of the world's quinine output. So British chemists have found a way of mass production of a substitute called melacrin.

Chemists have been asking what will happen to

persons who take the medicine before they get malaria, so members and friends of an ambulance unit took melacrin for a time and then allowed mosquitos to bite them. Only one has had malaria.

The chemists are still not satisfied. Their collection of continuous and the still not satisfied.

lection of captive mosquitos will not be complete until the man in Italy has sent them the three varieties he is pursuing.—Dispatch from Reuter, London

## CONCERNING THE EARLY STAGES OF CHRONIC GLAUCOMA

HARRY S. GRADLE, M.D., Chicago

THE exact number of blind people in these United States is not known accurately, but the proportion is probably about one to a thousand of population, or a little less. That estimate coincides fairly well with the statement that there are between 120,000 and 130,000 blind in the country. The same inaccuracy exists as to the causes of that blindness; but in recent years the increasing prominence of the causative role of glaucoma is coming to be recognized. The present estimates are that somewhere between 15 per cent and 20 per cent of blindness is due to various forms of hypertension; that is to say, between 18,000 and 25,000 people in the United States are blind as a result of glaucoma. And of that number, chronic glaucoma has been the cause in the proportion of ten to one.

It is a well-known fact that when chronic glaucoma is detected early, the ravages of the disease can be prevented in a fairly high percentage of cases, provided that the patient is faithful in respect to treatment and observation. But who is to detect it early? Obviously, the ophthalmologist. The general practitioner may suspect the existence of the condition, but lacks the necessary armamentarium and experience for accurate diagnosis before permanent damage has been done. A small percentage of nonmedical refractionists fall into the same class. The individual may have become thoroughly glaucoma-conscious through the fairly widespread publicity campaign, but the majority of such have a mental and not an ocular hypertension. So it all falls back into the lap of the ophthalmologist, who must not fail his people by lack of knowledge or by careless observation.

All patients seeking ophthalmic advice have something wrong with them, either subjectively or objectively; otherwise they would not come to us for help. Among those people, glaucoma is found to be present in between 1 and 2 per cent, and consequently every ophthalmic patient (past the age of 30 years) is a glaucoma suspect, unless proved otherwise. And the negative proof is sometimes more difficult than the positive. All ophthalmologists diagnose a full-blown case of chronic glaucoma without trouble, but recognition of the pre-glaucomas and the early chronics requires diagnostic acumen. In a suspected case, naturally the first recourse is to the tonometer, but that valuable instrument can give misleading information.

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 5, 1943.

have the records of five patients who have been under observation upward of four years, who were originally diagnosed as early chronic glaucoma, either in my office or elsewhere by competent ophthalmologists. The diagnoses were made upon tonometric readings in the upper thirties, in one case up to forty-three, but without visual or visual field disturbances. Naturally, pilocarpine was used, which normalized the tension and held it within the so-called normal range. After periods ranging from several weeks to several months, the patients discontinued the miotics, contrary to ophthalmic advice. In these specific cases there has never been a recurrence of the hypertension, nor have any functional disturbances ever developed. In two of them a mydriatic (euphthalmine) was used later without causing any increase in intra-ocular pressure.

Here, then, were five cases of what appeared to be early chronic glaucoma with hypertension but without functional change. Despite the lack of continued treatment, the hypertension subsided spontaneously and in four years time no further indication of glaucoma has developed. How can the facts of that seeming contradiction be reconciled? By the lack of infallibility of any regulatory mechanism. The regulation of normal intra-ocular pressure is the result of the functioning of a most delicate and complex mechanism, much of which is not yet understood. The diurnal variations in pressure in the normal individual indicate that the regulatory mechanism is not inflexible, but is capable of adjustments in accordance with the requirements of various conditions. Ordinarily the pressure variations are small, but it is easily conceivable that conditions could necessitate a temporary expansion of the limits, either upward or downward. Note the hypotension subsequent to an iritis. Regardless of hypothetic explanations, the fact exists that temporary intra-ocular hypertension, lasting from hours to weeks, producing no measurable functional damage and subsiding spontaneously. does occur.

This is a dangerous fact, if it is not recognized that the condition occurs only in exceptional cases. In the average case, such increases in pressure, even when not accompanied by demonstrable functional changes, are the forerunners of chronic glaucoma. The two forms can be differentiated only by refusal of the patient to persist in the use of miotics and by long-continued observation. Inasmuch as the non-pathologic increase in pressure here reported

is the exception rather than the rule, the visual welfare of the patient must be safeguarded by the use of miotics. It is far better to keep a normal eye under a weak miotic than to permit a glaucoma to develop through neglect of that precautionary measure.

For the past fifteen years we have been measuring the intra-ocular pressure tonometrically before and after the use of mydriatics in every individual past the age of thirty years. In 1935 I reported the results of this procedure on 1,000 eyes and found that 2.8 per cent of such individuals developed hypertension after pupillary dilatation. Some were frank early glaucomas that responded positively to dilatation, as well as to other provocative tests. In others, a positive diagnosis of glaucoma could not be made and we were forced to classify them as pre-glaucomas. I proposed this term in 1924 on a somewhat theoretic basis, and it has taken some years to produce actual proof of its existence.

A pre-glaucomatous eye is one that does not present a definite pathologic picture, but does vary sufficiently from the absolute normal to arouse suspicion. Subjectively there are no symptoms. Objectively, the absolute depth of the anterior chamber may be somewhat less than the eye of the patient would indicate, or the angle of the anterior chamber is so acute as to border on the lower limits of the normal. From our goniometric measurements we believe that an angular value of less than 7 degrees is pathologic. The pupillary reactions are normal, albeit somewhat slow. There is no pathologic cupping of the disk, nor other visible evidence of intra-ocular pathology. The visual fields, both peripheral and central, are normal, as is dark adaptation. However, upon instillation of a mydriatic, the intra-ocular pressure increases 12 or 15 or 20 mm. Hg, but is easily controlled with miotics. Other provocative tests may or may not be positive. As can be seen, the majority of evidence justifying a diagnosis of pre-glaucoma is on the negative rather than the positive side. Even a threehour tension curve may show no abnormalities.

How, then, can we confirm the existence of such a condition as pre-glaucoma? Only by willful disobedience of the patient and long-continued observation. I have the records of three patients in whom I made the diagnosis of pre-glaucoma three to six years ago. They were given weak miotics to use and were warned of possible danger, although evidently not impressively enough. All were faithful with the miotics for three months up to two years, during which time no evidence of a developed glaucoma could be found on repeated examination. They then disappeared and were

not seen again for two, two and a half, and four years. In every instance, during that time, typical chronic glaucoma had developed and caused visual acuity and visual field losses.

In contrast to those three positive cases, we have had many cases in whom pre-glaucoma was diagnosed who were faithful in the use of weak miotics, and who, over a period of years, have never developed any subjective or objective findings of chronic glaucoma. Maybe they would not have done so anyhow, but I feel that I have prevented loss of sight in at least some of them by the tentative diagnosis of pre-glaucoma and the preventive therapeutic measures adopted.

This question of the presumptive diagnosis of pre-glaucoma or early chronic glaucoma is not one of the most difficult decisions that have to be encountered in the whole clinical realm of glaucoma, for if the suspicion exists that the patient has or is subject to increased intra-ocular pressure, it is simple to institute a regular regime of miotic care that in the majority of instances will prevent damage. But if the condition is allowed to exist until actual hypertension and its resultant damage have occurred, then not only is the condition more difficult to stabilize, but also intensive miosis and even surgery may be required.

One final word concerning the use of miotics in pre-glaucoma and early chronic glaucoma. The less frequent the use, and the weaker the strength of the miotic required to normalize intra-ocular pressure, the brighter is the ocular future of the patient. Too strong a miotic used too often will produce damage just as surely as will an error in the reverse direction. Consequently a tension curve under miotics is of greater value than is a curve without miotics. There is a happy balance that can be reached by careful individualized study, which in turn means the difference to the patient between lifelong light and perpetual dark.

#### Discussion

Algernon B. Reese, M.D., New York City—Dr. Gradle has called our attention to a number of interesting and worth-while features of glaucoma diagnosis and treatment. He has always been an advocate of early diagnosis of the disease because its inroads are irrevocable and its treatment more effective in the early stages. He places responsibility for early diagnosis in the lap of the ophthalmologist, stating that every patient over 30 years of age is a glaucoma suspect. This is particularly true, as we know, in certain instances; namely, in patients with hyperopia of any appreciable amount, patients with shallow anterior chambers, and patients with high normal intra-ocular pressure.

I should like to emphasize three other categories which are also suspect: first, those in whom the cen-

tral blood vessels of the disk are pushed more to the nasal side and the angle made by the superior and inferior branches of the central retinal vessels are more obtuse: second, individuals in whom the difference in the intra-ocular pressure of the two eyes is greater than 4 to 5 mm. of Hg. No one has yet told us what the normal difference in the pressures of the two eyes is. It would be valuable to have this information established. I surmise that a difference of 4 to 5 mm, of Hg is abnormal and, when noted, should be considered a potential omen of glau-

The third category comprises any patients who show symptoms that are unilateral. In this I have noted in three instances that unilateral tearing was

the first symptom the patient presented.

Dr. Gradle also mentions the fact that tonometers can give misleading information. I should like to emphasize the importance of having tonometers checked because the readings of different tonometers vary considerably. In New York the instruments can be checked at a station for this purpose which is sponsored by the National Society for the Prevention of Blindness.

Dr. Gradle mentions an interesting group of patients to which my attention has never been drawn i.e., those whose intra-ocular pressure undergoes a temporary rise to a level above normal, the duration of the rise varying from hours to weeks. This produces no measurable functional damage. warns, though, that the spontaneous disappearance of this tendency toward glaucoma is an exception and that usually it is the forerunner of chronic glaucoma. Since having this group of cases called to my attention, I have been able to locate two such instances more or less recently seen. In one case the pressure in the left eye was 45 mm. of Hg, while that in the right was normal. Pilocarpine drops were prescribed for one year, during which time the pressure in each eye was normal. The drops were discontinued, and for the past three years at regular intervals there has been no rise noted in the intraocular pressure. The fields of vision are normally full. After the blind spots had been charted several times. I noted a tail developing on each blindspot above and below. These tails elongated at the later examinations, and it was finally conclusively determined that they represented angioscotomata. This feature is mentioned because in cases where intelligent, cooperative, and observing patients are repeatedly examined they may detect such angioscotomata around the disk as they become more familiar with the procedure, and these angioscotomata may be confused with glaucoma scotomata.

Another instance of a temporary rise in intraocular pressure was observed in a patient whose right eye measured 35 mm. of Hg and the left eye 30 mm. of Hg. Pilocarpine drops were prescribed and used for six months. They were discontinued, and for the past two years at regular intervals no rise in intra-ocular pressure has been noted. These two cases, therefore, seem to bear out Dr. Gradle's contention that there exists a group in which the increased intra-ocular pressure may be transitory. Dr. Schoenberg might explain these on the basis of temporary emotional stress in individuals predisposed to glaucoma.

We are very appreciative of Dr. Gradle's most interesting paper, which has given us a number of phases of this absorbing subject to think about.

## COLGATE EXHIBIT REVEALS THAT SOLDIERS FOLLOW HEALTH RULE OF 1863

Pictures from today's battle fronts show that many of Uncle Sam's fighting men are following, probably by chance, a health rule laid down for soldies.

soldiers eighty years ago.
"Let your beard grow so as to protect your "Let your beard grow so as to protect your support of the soldiers support support of the soldiers support support of the soldie throat and lungs," says the rule, one of eleven suggested for soldiers of the Civil War and approved by Dr. C. B. Coventry, ex-president of the New York State Medical Society. Printed on a pocket-size card, the rules are on display in the Colgate University library among latters and documents University library among letters and documents in an exhibit, "The United States at War, 1775-

"To cure or prevent sore feet, rub bar soap on the inside of your stockings," reads another of

rules.

The rest of the nine are rules commonly ac-

cepted today.

Original war letters and papers of such generals as Washington, Horatio Gates, Lighthorse Harry Lee, William Henry Harrison, Andrew Jackson, Zachary Taylor, Robert E. Lee, Grant, Sherman, Longstreet, and Joseph E. Johnston, and such other figures as Franklin, Jefferson, Madison, Monroe, John Hancock, and John Quincy Adams

are included in the exhibit.

Among the more interesting letters are those in which General Gates writes relative to the "Conway Cabal" to supplant Washington as commander-in-chief of the Army, Zachary Taylor tells the overseer of his plantation early in 1845 that war with Mexico is out of the question, Grant writes curtly to the provost marshal of Baltimore concerning the latter's treatment of released Confederate prisoners, and General Johnston refutes Jefferson Davis' statement that war could have been continued after Lee surrendered.

Also included is a first copy of "Dixie's Land," which Dan D. Emmett, a staunch Union man. wrote in 1860, only to see it adopted shortly afterward as the official battle song of the south.-

## CLINICAL STUDIES OF SULFAMETHAZINE

WALSH McDermott, M.D., D. Rourke Gilligan, M.S., Charles Wheeler, M.D., and NORMAN PLUMMER, Maj., (MC), AUS, New York City

CULFAMETHAZINE,\* a dimethyl derivative of sulfadiazine, has been subjected to clinical trial in England during the past year.1,2 From these studies of its use in a total of 120 patients with various infections, it was reported that the drug had high therapeutic effectiveness and low toxicity. In vitro and in vivo experimental studies have shown that it has bacteriostatic activity quantitatively similar to that of sulfadiazine3 or of sulfapyridine.4

Of particular interest is the fact that sulfamethazine and its acetyl† derivative are more soluble in acid urine than are sulfadiazine and acetylsulfadiazine, respectively.4,5 In apparent accord with these solubility characteristics, Macartney et al.1 in their clinical trial of sulfamethazine found no crystalluria or renal complications attributable to the drug.

If sulfamethazine has the same therapeutic effectiveness as has sulfadiazine, the greater solubility of the former drug and its acetyl derivative in the acid ranges of urinary pH would appear to constitute a distinct advantage. Crystalluria and resulting urinary-tract complications have been the most frequently encountered untoward reactions accompanying the use of sulfadiazine. 6,7,8,9 Whereas it has been shown recently 10,11 that crystalluria and resultant renal complications from sulfadiazine can be prevented with appropriate adjuvant alkali therapy, it is obvious that a similar sulfonamide requiring no adjuvant alkali would be more desirable.

On the basis of this single apparent advantage of greater solubility in acid urine, it seemed that sulfamethazine<sup>‡</sup> warranted further clinical trial. Accordingly, 34 patients with various infections (Table 1) were treated with this drug and studies of its pharmacology, toxicology, and therapeutic value were made.

## Blood Sulfamethazine Studies

Of the 34 patients who received sulfamethazine there were 27 with normal renal function who received an initial dose of 1 or 2 Gm. of the drug followed by 1 Gm. at four-hour intervals-i. e., 6 Gm. daily. Blood samples, usually from three to eight specimens drawn on different days, were

From the New York Hospital and Department of Medicine, Cornell University Medical College.

N4-acety'l derivative. ‡ Sulfamethazine was kindly supplied by Lederle Laborastudied for sulfonamide concentrations in all of Analyses were made by the these patients. method of Bratton and Marshall.125

The average blood levels of free sulfamethazine of the individual patients in this group who received 6 Gm. a day of the drug varied from 1.8 to 17.4 mg. per cent (Table 2). This wide range of free blood level in different patients was due largely to the striking variation in the degree to which the drug was acetylated, i. e., from 1 to 74 per cent (Table 2). The total blood levels for the individual patients varied considerably less than the free blood levels, ranging from 6.2 to 17.6 mg. per cent. The blood concentrations of both free and total sulfamethazine and the degree of acetylation were usually fairly constant during therapy in a given individual.

There were 6 patients in whom from 42 to 74 per cent of the blood sulfamethazine was acetylated and in whom the blood levels of free sulfamethazine were consequently all less than 5 mg. per 100 cc. (Table 2). In addition 2 of 3 patients with 32 to 35 per cent acetylated sulfamethazine had free blood levels averaging 4.1 and 5.1 mg. per cent (Table 2). All of the 18 patients with 1 to 25 per cent of acetylated sulfamethazine had free blood levels of 7.5 mg. per cent or more. In the group of 7 patients who received daily amounts of sulfamethazine other than 6 Gm. or who had pre-existing renal insufficiency, 7 to 30 per cent of the blood sulfamethazine was in the acetyl form.

## Urine Sulfamethazine Studies

Chemical analyses of twenty-three urine specimens from 19 patients on the second to fourth day of medication showed from 32 to 93 per cent (61 per cent average) of the urinary sulfamethazine in the acetyl form. In 6 of the 19 patients more than 70 per cent of the urinary sulfamethazine was acetylated; 5 of these 6 patients had a high percentage (32 to 72 per cent) of acetylsulfamethazine in the blood.

Seventy morning urine specimens from 25 patients were examined microscopically for crystalluria due to sulfamethazine medication. Approximately 90 per cent of the urinary pH values, tested with nitrazine paper, were acid of pH 5 to 6. Sixty-five of the seventy specimens showed no crystalluria. Two acid urine specimens from 2 patients showed large numbers of crystals

<sup>\* 2-</sup>sulfanilamido-4,6-dimethylpyrimidine.

which were shown to be chiefly acetylsulfamethazine on analysis by the Bratton and Marshall method.<sup>12</sup> The filtrates of the urines in these instances showed very high percentages (87 and 93 per cent) of the dissolved sulfamethazine in the acetyl form. One acid urine specimen from each of three other patients also showed crystals believed to be sulfonamide precipitates. In all 5 patients with proved or suspected crystalluria from the drug, the degree of acetylation in the blood and urine was high. As noted below, one of these patients showed gross hematuria of short duration.

## Comparative Studies of Acetylation of Sulfamethazine and Sulfadiazine

In 3 patients who acetylated sulfamethazine to a high degree, the drug was replaced by sulfadiazine in the same dosage. In all of these patients a strikingly lower degree of acetylation occurred with the latter drug (Table 3). Whereas the total blood sulfonamide level was approximately the same with both drugs, the blood level of free drug was much higher during the period of therapy with sulfadiazine.

## Toxicity

Four of the 34 patients who received sulfamethazine showed one or more toxic reactions. One patient developed a rash accompanied by fever; another had a rash, fever, and leukopenia (a leukocyte count of 2,600); another had leukopenia (a leukocyte count of 2,700) without other reaction. There was no granulocytopenia associated with the leukopenia in either instance, and the leukocyte counts of both patients rose promptly to normal after sulfamethazine was discontinued. In a patient with aplastic anemia with a leukocyte count of approximately 2,000, no effect of the drug on the leukocyte count was The fourth instance of toxicity was gross hematuria and albuminuria occurring in a patient on the fourth day of therapy, with microscopic hematuria continuing for two days after the drug was stopped. This patient had shown a high degree of acetylation (52 to 72 per cent) of the blood sulfamethazine, and crystals believed to be sulfonamide crystals were present in the

urine specimen, showing gross hematuria. There were no instances of nausea and vomiting attriutable to the drug. No significant changes in the erythrocyte counts occurred during therapy.

#### Clinical Results

In the group of 18 patients who received 6 Gm. daily of sulfamethazine (Table 2) and who showed the higher blood levels of free drug, the clinical response was similar to that usually seen with similar doses of sulfadiazine. Infections caused by organisms known to be sulfonamide-susceptible, such as the pneumococcus, responded well; patients with infections not usually benefited by sulfonamide, such as atypical pneumonia, were not benefited by sulfamethazine.

Three of the 7 patients with average blood levels of less than 5 mg. per cent (Table 2) had pneumococcal lobar pneumonia. In all of these three, the clinical course was complicated by incidents suggestive of relapse or progression of the infection. One of these patients died—a 61-year-old Negro man with type I pneumococcal pneumonia and bacteremia, who was admitted on the fourth day of his disease. Although during the latter part of his course he received sulfadiazine and antipneumococcus serum, the question arises whether the course of the infection might have been different had the patient not had so low a blood level of free sulfonamide (due

#### ARMY MEDICAL LIBRARY

The Surgeon General's Library, or the Army Medical Library, as it is now officially called, has been for generations in a class to itself. Not only is it the greatest collection of medical literature in the world, but its great catalogue and the Index Medicus and its successor, the Cumulative Index Medicus, the latter a joint undertaking with the American Medical Association, has made this collection, and incidentally other medical libraries. extremely useful. We doubt that many realize the full value of these indices. We have always had them, and, like life, liberty, and the pursuit of happiness, we take them for granted. One should read Oliver Wendell Holmes' delightful e-say on medical libraries to see what a library was like before the *Index Catalogue*. It was written in 1878 when the "Specimen Fasciculus of a Catalogue of the National Medical Library" had just made its appearance. Dr. Holmes compares "back volumes" that were not indexed to a "lock without a key, a ship without a rudder, a binnacle without a compass, a check without a signature, or a greenback without a goldback behind it.

It is hard to realize the wide scope of the Library's possessions. A number of years ago when the late Sir Kederath Das, of Calcutta, was the guest at a Washington meeting of the American Gynecological Society, we asked him what he wanted to see on his free afternoon. He replied that the only thing he really wanted to see in America was the Surgeon General's Library. When we reached the Library we introduced him to Mr. Toepper, who showed us around. In the course of the visit he took us up in the stacks to the Hindoo section, where there were more Hindoo books than Dr. Das had seen in India. We were interested to hear that the most used book in Dr. Das' library in Calcutta was the Index Catalogue. He had all three se-

On another occasion we visited the Library with Professor Miles Phillips, who is quite an authority on old books, especially those pertaining to the history of obstetrics. Dr. Claudius Mayer showed us some recent acquisitions from Russia, books that had belonged to the late Czar, and among them were Russian editions of old English obstetricians and men-midwives. Professor Phillips, who knew the works of these men well, could not believe that such editions of their work existed.

From our medical school days we have looked upon the Library as one of those perfect things that has existed as such always. It was quite a shock when we learned that before John Shaw Billings' time it was a collection of only a few thousand books. Colonel Jones, the present librarian, has a sketch of the early history of the Library, together with its present status and future plans, in a recent number of the Journal of the American Medical Association (J.A.M.A. 132: 1074, 1943). We were interested to learn that the Library has had its ups and downs. The low point of the Library occurred between the years of 1930 and 1936. Interestingly enough, the only book that we ever failed to find in the Library was published just before this period. While the war has postponed the erection of the new building, authorization for which has already been passed by Congress, it has benefited the Library in another way. rare-book collection has been sent to Cleveland for safety. This gives some needed room in the old building, which has long since been overtaxed, and it also affords an opportunity for rehabilitating these priceless volumes. Instead of being packed away in bombproof vaults, the rare books in Cleveland are being restored and are also available to students. Photostats and microfilms can be produced in Cleveland as readily as ever.-Virginia Medicine Monthly

to high acetylation of the sulfamethazine) on the first day of therapy.

The remaining 4 patients with low blood levels had either self-limiting infections such as acute pharyngitis or infections not usually responsive to sulfonamide therapy. Therefore, the therapeutic effectiveness of sulfamethazine in these patients was impossible to evaluate.

There was one other death in the entire group of 34 patients who received sulfamethazine. The patient was a 30-year-old woman with type I pneumococcal pneumonia complicated by pyelonephritis and anemia. She received type-specific antipneumococcus serum and intravenous sodium sulfadiazine in addition to oral therapy with sulfamethazine. Blood levels of free sulfonamide were constantly high (average 18.3 mg. per cent), so that there is no reason to believe that the sulfonamide therapy was inadequate.

#### Discussion

Several investigators1,4,13,14,15,16 have viously reported that sulfamethazine and also sulfamerazine\* are acetylated generally to a greater extent than is sulfadiazine. It has also been reported1,4 that some patients treated with sulfamethazine show particularly low blood levels of free drug associated with high levels of acetylated drug. The incidence of this finding was not stated in these reports.1.4 In our series, 7 of 27 patients receiving 6 Gm. of sulfamethazine daily had average blood levels of free drug of less than 5 mg. per cent (1.8 to 4.8) associated with an average of 55 per cent (34 to 74) of the total drug in the blood in the acetylated form. In contrast, following the same dosage of sulfadiazine, the lowest average blood level of free drug in 79 patients was 4.5 mg. per cent.17 Furthermore, the acetylated sulfadiazine in the blood is almost never greater than 25 per cent of the total.18

Because of the marked variability in the degree of acetylation of sulfamethazine in different patients, the dosage required to maintain a given blood level of free drug varies and is unpredictable. It is of interest that Hall and Spink 16 have recently reported difficulty in maintaining adequate blood levels of free sulfamerazine in some patients due to excessive conjugation of this drug. It is further to be noted that because of excessive acetylation of sulfamethazine the concentration of acetylsulfamethazine in the urine of some of the patients in our study became so high that crystalluria, in one instance associated with renal complications, occurred even in the presence of blood levels of free drug of less than 5 mg. per cent. Conversely, with much higher blood levels of free sulfamethazine,

crystalluria did not occur in patients in whom the drug was not acetylated excessively. The absence of crystalluria under these latter circumstances was predicted from the solubility characteristics of the drug<sup>5</sup> and its acetyl derivative.<sup>15</sup>

In our small series treated with 6 Gm. of sulfamethazine daily there were 3 patients with pneumococcal pneumonia with low free blood levels of drug consequent to high acetylation. In these patients the clinical course was complicated by relapse or progression of the infection. The question arises whether the clinical course in these pstients might not have been more satisfactory had they been treated with the same dosage of sulfadiazine, with consequently higher blood levels of free drug. It may also be of importance that sulfamethazine is bound<sup>19</sup> in the plasma, presumably to plasma albumin, 20 to a much greater extent than is sulfadiazine, 19,20,21 so that for a given blood level of drug the level of dialyzable (i.e., unbound) drug in the plasma and in the tissues is only approximately a third to a half as great for sulfamethazine as for sulfadiazine.19 Moreover, evidence has been presented20 which indicates that only the dialyzable portion of a sulfonamide in the plasma is bacteriostatically effective. This difference in the degree of binding of these two drugs which show approximately equivalent in vitro bacteriostatic activity3 would appear to be of therapeutic significance and might be particularly important in patients with low blood levels of free (i.e., unacetylated) sulfamethazine.

Because of this unpredictable, high acetylation, which carried with it the twofold disadvantage of a low blood level of free drug and a high urine level of acetyl derivative, it would seem that sulfamethazine is not so satisfactory a sulfonamide as is sulfadiazine. This superiority of sulfadiazine is particularly marked now that it has been shown that adjuvant alkali therapy will prevent the crystalluria and resulting urinary-tract complications arising from its use. 10,11

## Summary and Conclusions

- 1. The pharmacology, toxicity, and therapeutic effectiveness of sulfamethazine have been studied in 34 patients with various infections.
- 2. An importantly large percentage of these patients showed very high acetylation of sulfamethazine.
- 3. This high degree of acetylation resulted in exceptionally low blood levels of free drug from the 6-Gm. daily dosage of sulfamethazine.
- 4. Crystalluria, in one instance accompanied by gross hematuria, occurred in patients who showed this excessive acetylation of sulfamethazine.

<sup>\* 2-</sup>sulfanilamido-4-methylpyrimidine.

2. The substance is not previously present in the body.

3. The substance should not affect the con-

dition being studied.

生えごごごだい

· 一年一年一年一年一年一年一年一年一年一年

- 4. The substance should be quickly inactivated or eliminated to enable duplicate tests to be repeated within a short time interval without injury to the patient.
- 5. There should be a minimum or a complete absence of side-effects.
  - 6. The method should be simple.
- 7. The end point should be distinct and easily perceived.
  - 8. The drug should be generally available.
- There should be no effect on the hemodynamics from the dosage used.
- 10. The method should not be dependent upon the patient's cooperation.
- 11. Failures with the agent should be minimal.

# Photoelectric Dye Method in Relation to Requirements

- 1. The substance must be nontoxic in the amounts used.—Methylene blue (tetramethylthionin hydrochloride) is commonly used by urologists for testing kidney function, and is administered in amounts varying from 10-30 cc. of a 1 per cent solution without any apparent ill effects. This substance was reported to have been given by mouth to dogs in amounts of 270 mg. per kilogram for twenty-eight days without any demonstrable effect.6 Hartmann, Perley, and Barnett<sup>7</sup> confirmed Wendel's<sup>55</sup> work on sulfanilamide methemoglobinemia with methylene blue administered in amounts of 400 mg. per day in six divided doses to children weighing less than 20 kilograms and stated that to those weighing more, up to 800 mg. may be given safely in divided doses per day. Toxic effects have been reported with amounts of 20 to 50 mg. per kilogram of body weight, administered parenterally,9 whereas the amounts used in our series never exceeded 1.5 mg. per kilogram of body wieght. It is apparent from our experience and the data just cited that the amounts used in this test are well within the limits of safety. We have not encountered any of the hemolytic effects reported by Huyghebaert, 10 or the hives and burning of the lips described by Wendel, 59 or any ill effects following rapid intravenous injection of the dye. At no time was there evidence of renal irritation found after its use.11 Perivenous injection causes a slight painful reaction which subsides after a few hours without any local necrosis.
  - 2. The substance is not previously present in the body.—This fact is self-evident with

regard to methylene blue, or other dyes used, except methemoglobin.

- The substance should not affect the condition being studied.—It has been frequently reported by workers in this field that some of the substances advocated may aggravate conditions present, which contraindicate their use. For example, sodium dehydrocholate (decholin) is known to materially aggravate any existing severe hepatic injury and is thus contraindicated as a test in cases of obstructive jaundice or severe liver damage.12 Likewise, this substance is held to be contraindicated in cases of bronchial asthma. Collapse, as a result of respiratory failure, has occurred with the use of sodium cyanide.13a,b Carbon dioxide, advocated as a measure for lung-to-respiratory-center time, often aggravates pre-existing tracheobronchial abnormalities. The severe local irritating effects of saccharin and ether,14 with production of venous thrombosis or phlebitis, are well known to workers in this field. As already indicated above, the use of methylene blue as a test substance is free from these objections.15
- The substance should be quickly inactivated and eliminated to enable duplicate tests to be repeated without injury to patient.—Although methylene blue is not entirely eliminated from the body through the kidneys for periods varying from twenty-four to seventy-two hours, it is converted into the leuko-derivative through the reducing activity of the blood. Under usual conditions the complete conversion to the leukoderivative takes approximately two minutes to be consummated. This amply suffices for the purpose of the test, since the longest circulation time reported in our series was in cardiac cases with severe decompensation, and the longest time was sixty-four seconds. Tests have been repeated within five minutes with satisfactory results.
- 5. There should be a minimum or absence of side-effects.—In the series studied at the Goldwater Memorial Hospital one patient, in whom the test was performed in a sitting position, complained of slight dizziness when he stood up immediately after the completion of the test. Since then we have routinely made this test with the patient in the supine position and no reactions of any kind occurred. No subjective discomforts have been reported by the individuals tested.
- 6. The method should be simple.—This method does not involve any more difficult procedure than that associated with most subjective methods. The amount of dye solution used rarely exceeded 5.0 cc. Often we were able to obtain results with 2 or 3 cc., which naturally shortened the time of injection considerably. Only in cases of severe decompensation, where

## CLINICAL STUDIES OF CIRCULATION TIME WITH OBJECTIVE (PHOTOELECTRIC CELL—DYE) METHOD

BENJAMIN JABLONS, M.D., New York City, Jules Cohen, M.D., New York City, and Morgan Y. Swirsky, M.D.,\* New Haven, Connecticut

THE determination of the circulation time L has proved to be of considerable value in clinical medicine. It is commonly defined as the time required for a foreign particle introduced into the circulatory stream to travel to a given point of detection.

It has been determined in a variety of ways. A great many methods (subjective) depend upon the cooperation of the patient; others are objective in that they can be demonstrated without such assistance. When participation of the subject is feasible, it is often possible to obtain a fairly accurate measure; however, even with such cooperation it is sometimes difficult to obtain this measure because of circumstances beyond the control of the subject. It is for this reason that objective methods have been earnestly sought.

A number of methods were used heretofore for this purpose. These have been reviewed up to 1931 by Blumgart1 and more recently briefly reviewed by Bellis;2 and by Koster and Sarnoff3 in 1943. The use of dyes for this purpose has been reviewed by Jablons and Cohen<sup>40</sup> in 1943.

### Method and Technic

Briefly, our method of study consists of the adaptation of a photoelectric cell, and a light source, to the measurement of circulation time.4 The principle involved is that light transmitted through translucent living tissue may be modified by the passage of a dye injected into the blood stream, and this modification may be detected by the reduction of current set up in a photoelectric cell by the transmitted light.

We have utilized for the light source an ordinary pencil flashlight bulb powered by a single or double 3-volt dry-cell battery, mounted on a light carrier, which is attached to a head-mirror type of band by means of a universal joint. The photoelectric cell (35 mm. in diameter, of the selenium barrier layer type) is connected to a pointer type of galvanometer with a fullscale deflection at 10 microamperes. The entire apparatus is self-contained in a portable wooden casing with cover and carrying strap. †

The dye employed was a 1 per cent solution

of methylene blue in distilled water put up in sealed ampules of 10 cc.‡

Patients were placed in the supine position when ambulatory, otherwise the test was performed at the bedside. The head band containing the photo cell and the light source was attached firmly and the photo cell adjusted so that its active side was in contact with the pinns of the ear, while the light was placed directly behind the ear. The light was so adjusted that maximum transmitted light centered on the surface of the photo cell. When the light was turned on, the needle of the galvanometer usually showed full-scale deflection. In fair-skinned types it was necessary to reduce the amount of current registering by turning the potentiometer knob toward the O point until the needle registered 70-80 on the scale. Although sensitivity is greatest at full-scale deflection, we have found it more satisfactory to maintain the needle at 70-80 so that deflection in either direction is easily recognized.

The patient is prepared for injection in the usual manner observing a precaution emphasized by previous investigators—i.e., that the arm be placed so that the antecubital vein should be approximately on a level with the right auricle of the heart. A standard 5- or 10-cc. syringe with an 18- or 20-gauge needle is used. A tourniquet is applied to facilitate entering the vein and as soon as the needle is in the vein (a small amount of blood is aspirated to be sure) the tourniquet is released. After a pause of a few seconds the entire contents (2-5 cc.) are injected rapidly into the vein.

The time of injection should not exceed two seconds, and, whenever possible, should not require more than one second. At the instant of injection the stop watch is started, and is stopped at the instant the deflection of the needle of the galvanometer is seen.

## Value of Method

It is generally agreed among most investigators 54,6 that certain qualifications are essential for a substance which is to be used intravenously for the determination of the circulation time. These requirements are:

1. The substance must be nontoxic in the amounts used.

other methods-viz .: that the average circulation time is prolonged in patients suffering from congestive heart failure. The average value is normal in those who have not experienced failure or who have recovered from failure. This may be the explanation for the slight difference present only in the cardiac group, compensated and noncompensated, studied at City Hospital and Goldwater Memorial Hospital. In the first-named institution patients are admitted in varying stages of acute cardiac failure, without and with previous similar episodes. These patients remain in the hospital from two to six weeks and are often transferred to a hospital for chronic diseases and are considered clinically compensated. There is a slight discrepancy in the limits of normal between the two series reported in the groups classified as compensated cardiacs. This may be due to individual differences in determinations or slightly different criteria as to what constitutes clinical compensation. This would account for some of the borderline cases reported in this series, and would explain the upper limit of seventeen seconds in the compensated group in the Goldwater Memorial series, as compared with the upper limits of 20 seconds in the City Hospital group (Fig. 1).

The circulation times of the bronchial asthma groups in both institutions show very close agreement, being 13 and 13.3 seconds at City and Goldwater Memorial Hospitals, respectively, both being well within the limits of normal. Al-

though associated with intense dyspnea, diffuse rales, and cyanosis, this normal circulation time sharply differentiates bronchial from cardiac asthma, which is always characterized by a prolonged circulation time. In general, what is true of bronchial asthma is also true of other pulmonary conditions-e.g., emphysema, pulmonary fibrosis, pneumonia, pleurisy with effusion, tuberculosis, bronchiectasis, and neoplasms.

We have confirmed with this method other previously reported observations of the increased velocity of the blood flow in cases of hyperthyroidism, and the retardation—i.e., the shift to normal-produced by adequate iodine administration or surgery.

This method has proved of value as an index of therapeutic response to digitalis, diuretics, and other measures employed to combat heart failure.

### Summary

- An objective method is herewith presented for the determination of the circulation time. based on the principle of the modification of light transmitted through translucent tissue to a photoelectric cell, by intravenously injected nontoxic dye, and the resulting change produced in the electric current.
- This method fulfills all of the requirements stipulated for an agent utilized for such determination.
- The results obtained in 200 cases in 2 different institutions agree generally with those reported for subjective methods under ideal conditions.
- This method has the added advantage of being independent of patient cooperation, making its use possible in cases of stupor, coma, aphasia, language difficulties, mental defectives, infants,
- It is possible with this method to obtain accurate recorded data.

pooling of the blood is suggested by the increased venous pressure, did we get the impression that larger amounts might have caused a much greater deflection of the galvanometer The detector apparatus in our method is a simple photoelectric cell, as described above. connected with thin wires to a sensitive indicator instrument (galvanometer) away from the body in contrast to the inconveniences associated with the use of the fluorescein and radioactive sodium and radium deposit methods.

The end point should be distinct and easily perceived.—The deflection of the needle occurs instantaneously as the modification of the current is produced. The extent of the deflection varies, however, with a number of factors. In anemic and thin individuals it is considerably greater than in heavy plethoric types. Since the photo cell casing amply shields the cell from extraneous light, modification of the current is reflected by the change in the galvanometer needle and the greater the change produced by the dye the more striking the deflection.

8. The drug should be generally available.-Urologists and internists have used the drug for many years for testing kidney function and for other therapeutic purposes. It is available through numerous pharmaceutical houses.

There should be no effect on the hemodynamics from the dosage used.—Studies made on the pulse rate and blood pressure in a number of cases did not show any appreciable changes.

The method should not be dependent upon the patient's cooperation.—Patients who are in stupor, in coma, or have sustained cerebral accidents with resultant aphasia; patients who have congenital or acquired deaf mutism, language difficulty, or defective mental development; and infants all offer obstacles to all the subjective methods of determining circulation time. This method is in no way affected by these difficulties. Emotional perturbation and apprehension and the extreme discomfort and restlessness associated with bronchial asthma do not interfere with the successful performance of this test.

Failures with the agent should be minimal. -In initial studies, utilizing an apparatus with relatively fixed position of light source and photoelectric cell a few blank results occurred which we found were due to excessive compression of the tissues by the photoelectric cell and light On proper adjustment of the instrument, more easily achieved by the improved model now in use, and repetition of the tests, a satisfactory determination resulted in every case tested to date. In dark-skinned or deeply pigmented individuals light intensity sometimes be increased to insure success.

## Possible Sources of Error with This Method

It is essential with this method to assure an adequate concentration of dye in the blood to obtain a clear-cut deflection. When the dye is injected slowly a number of seconds may be required for the deflection to occur-sufficiently to rule out a possible artefact due to any other Occasionally a cough may produce a slight deflection which might be misleading if one is not sufficiently familiar with the typical swing which is produced by the appearance of the dye in the blood stream at the point of detection.

The injection of an amount of dye which through dilution interposes too little screening effect may fail to produce adequate deflection. This may occur in decompensated cardiovascular disease, or in polycythemia where the blood volume is considerably increased. This may be overcome by the use of an adequate amount of dye, usually approximately 5 cc. of a 1 per cent solution. Even in extreme cases of cyanosis, as in advanced heart failure, this amount of dye gives a satisfactory end point. When the tissue of the ear is held too firmly between the photo cell and the light holder the galvanometer needle may not move following the passage of the dyed blood as mentioned previously. We have assumed that this was due to a blanching effect of the area in question caused by compression which interfered with the free flow of blood and the dye which it contained. This proved to be the reason since the adjustment of the light and photo cell, and repetition of the test, always gave satisfactory response.

Table 1 gives a comparative analysis of studies in circulation time made at New York City and Goldwater Memorial Hospitals.

These figures emphasize the point previously suggested by other investigators employing

## THE MANAGEMENT OF INJURIES OF THE COMMON BILE DUCT

HERMAN E. PEARSE, M.D., Rochester, New York

INJURY of the common bile duct may be caused by ulceration from stones or from suppuration, but it most often occurs at operation. Occasionally this is during gastrectomy, but usually it is from clamping, tying, or excising the duct during cholecystectomy. Congenital anomalies, unexpected hemorrhage, or distortion of normal anatomy by infection may confuse the surgeon and lead to injury.

#### Prevention

The common duct will not be injured if it is clearly seen. The first necessity is exposure of the junction of the hepatic, cystic, and common ducts before clamping or cutting anything. If this rule is always followed, most of the hazards are eliminated. It may be helpful during this dissection to have a sponge clamp on the ampulla of the gallbladder to put slight tension on the cystic duct. After the relation of the ducts is defined, then and only then should the gallbladder be removed. There is a real advantage to ligating and dividing the cystic artery before the cholecystectomy, for it greatly reduces the bleeding and prevents obscuring the field by blood.

Strong traction on the gallbladder may pull up a loop of the common duct so that it looks like a continuation of the cystic duct. Clamping or excising this when the gallbladder is removed is the commonest method of ligating the common duct, which otherwise is rather hard to do. This accident can be avoided if only gentle traction is used to assist in defining the junction of the ducts.

In acute cholecystitis there is not only edema and swelling of the tissues but also apparent shortening of the cystic duct from the inflammation. These circumstances make adequate exposure difficult. Some surgeons advocate in these cases dissection of the gallbladder from above downward in order to develop it on a pedicle of the cystic duct. This is usually a bloody method. By using suction to keep the field dry, the usual technic of cholecystectomy can ordinarily be used even in acute cases.

Congenital anomalies may cause confusion for, while in 75 per cent of cases the cystic duct joins the hepatic at an acute angle, yet in 17 per cent they run parallel, and in 8 per cent the cystic duct twists in front or behind the hepatic duct. The abnormalities of the arteries are even more

frequent, the most dangerous being those cases in which the right hepatic artery lies in front of the common duct and runs parallel to the cystic duct.<sup>2</sup>

Unexpected hemorrhage deep in the wound is always alarming. It may follow the slipping of a clamp or tie off the cystic artery. In the effort to control the bleeding the hepatic duct near its bifurcation may be injured. Leahy, speaking of these injuries, says, "They are the result of excitement, I think. The cystic artery gets loose, bleeds into the deep operative field. The inexperienced operator fails to realize that by pinching the hepatic artery with his finger he can stop the bleeding artery, wipe the field dry, find the bleeding vessel, and control it accurately. Instead of this, he clamps wildy and picks up the hepatic duct in the clamp."

## Immediate Repair of Injury

If the operator discovers a damaged or severed hepatic or common bile duct, it should be repaired at once. In a divided duct the upper end is easy to find for it leaks bile. The lower end may be harder to locate but it should be sought until found, for it will never be any easier to identify than it is immediately after injury. The two ends of the divided duct should be united by end to end anastomosis. If a T tube is used, the vertical limb should not come out through the suture line but rather above or below it. A duct that has been crushed by a clamp should be allowed to heal over a tube. If it is badly macerated. the devitalized tissue may be excised and an endto-end anastomosis done. These methods of immediate repair will often spare the patient many complications later.

## Management of Stricture

The end result of unrepaired common duct injury is biliary fistula or stricture with increased pressure, liver damage, and cholangeitis. Stricture is a dreaded complication for it may have a devastating effect. It has been treated by the following methods:

1. Simple Dilatation.—This is unsatisfactory, for even though the stricture can be dilated at operation, it cannot be so treated repeatedly, and hence it reforms. The adage of "once a stricture always a stricture" applies here.

2. Excision of the Stricture with End-to-End Anastomosis.—If this can be done without tension on the suture line, it is the best method. Eliot<sup>4</sup> reports 38 cases with 24 good results.

3. Division of the Stricture with Plastic Repair

## LONGEVITY OF WAGE-EARNERS INCREASES IN FIRST YEAR OF WAR

Notwithstanding the casualties of war and the hardships on the home front, the average length of life among the many millions of Metropolitan Industrial policyholders, as computed from the prevailing mortality rates, rose to the all-time high figure of 64.18 years in 1942. This record, bettering the previous year's figure by nine months, marks the thirteenth successive year of gain in average length of life for this group. The increase has amounted to about 15 years in the quarter century since the first World War and to about 30 years in the past six decades.

The improvement in longevity has been greater in the industrial population than in the general population of the United States. In 1911 the policyholders were at a disadvantage to the extent of 6.4 years in the expectation of life at birth; the difference has diminished over the years and has now been virtually wiped out. This striking evidence of life conservation has greatly increased the forces now available to man the battle lines and the production lines.

The longevity of the American people, as reflected by this large group of insured persons, has reached such high levels that, on an average, half a century of life lies before a white boy of 16 or a young woman of 21 years. The so-called weaker sex has the greater longevity by about five years.

Another interesting fact to be noted in this table is that at age 35 the Industrial policyholder has on an average as many years before as behind him.

The next quarter century will undoubtedly bring many changes in the lives of the American people, and even those now in midlife will live to see many of these developments. Under present mortality conditions, white men 45 years of age and white women close to 50 still have a quarter century of Thus, the postlife before them, on the average. war world will be built not alone by those who are

now young, but also by those who have already accumulated the experience and wisdom of years.

The splendid record for longevity in 1942 among Metropolitan Industrial policyholders reflects the very favorable mortality experience during the year. Death rates of less than one per 1,000 were recorded for white boys of ages 7 to 13 years, and for white girls in the broad age range 4 to 18 years. Among the latter, phenomenally low rates of less than 0.5 per 1,000 were observed at ages from 9 to 12 years. Equally remarkable were the records in early adult life. Thus, among white females, death and the second series of the second seri death rates were less than two per 1,000 up to age 30, and less than three per 1,000 up to age 37. The present low level of the death rate, particularly at the younger ages, reflects in large measure the accomplishments of preventive medicine and the public health movement in recent decades. Here, indeed, is the reward for the constant effort to control tuberculosis, typhoid fever, diarrhea, and enteritis, the communicable diseases of childhood, pneumonia, appendicitis, and a number of other preventable causes of death. The greatly reduced death toll from accidents over the years has likewise saved large numbers of lives.

In 1942, as in other years, the longevity of colored persons was appreciably below that of the white. At age 5, the expectation of life of insured colored boys last year was about 4½ years less than for white boys; among girls the disparity amounted to seven years. The differences are even more striking when strated at the second seven years. striking when stated in terms of mortality. For example, at ages 27 to 32 the death rate for colored men in 1942 was at least twice that for white men. Among females at ages 14 to 25 years the death rate for the colored was more than three times that for the white. It is obvious that the colored population is still a fertile field for concentrated public health effort. This group is now experiencing the longevity that the white population did two decades ago. -Bull. Metropolitan Life Insurance Co.

## BIGGS MEMORIAL LECTURE ON APRIL 6

The Hermann M. Biggs Memorial Lecture, which is held annually in Hosack Hall at the New York Academy of Medicine under the auspices of the Committee on Public Health Relations, will be delivered this year on April 6 at 8:30 P.M. by Wilber A. Sawyer, M.D., director of the International Health Division of the Rockefeller Foundation. The subject of Dr. Sawyer's address will be "International Health."

This lecture is open to the general public.

# Diagnosis

## CLINICOPATHOLOGIC CONFERENCES

FOURTH MEDICAL DIVISION OF BELLEVUE HOSPITAL

Dale: December 16, 1943

Conducted by: Dr. Emanuel Appelbaum

C. H., a 58-year-old white handy man, was admitted to the Fourth Medical Division of Bellevue Hospital on October 18, 1943. He had enjoyed good health until two years before admission, at which time he began to suffer from sharp epigastric pain which occurred one to two hours after meals and which was relieved by alkalis. There was no associated nausea or vomiting, loss of appetite, or change in bowel habits and the patient received no treatment. During these two years the pain recurred from time to time and the patient lost 10 pounds in weight. Six months before admission the pain became increasingly severe and constant and was no longer relieved by alkalis. Three or four months later a smoker's cough which the patient had had for many years became quite severe and productive of a moderate amount of white phlegm but there were no hemoptysis, chills, fever, or night sweats. Two or three weeks preceding admission the patient suddenly developed a sharp pain in the lower left side of the chest. This pain was aggravated by coughing and radiated to the opposite side of the chest and to the back. There was some improvement in all these symptoms, including the cough, shortly before the patient sought admission.

The patient had had no significant previous illnesses. An injury to the left side of his chest at the age of 18 years resulted in permanent deformity. His general habits were good and his family history was noncontributory.

Physical examination on admission revealed a fairly well-nourished and well-developed white man who did not appear acutely ill. The temperature was 99.2 F., pulse 88, respirations 20, and the blood pressure 100/60. Examination of the head and neck revealed no abnormalities. The chest showed flattening of the left anterior portion. There was slight dullness of both interscapular areas and the right base and slight diminution of breath sounds at the right base. No rales or wheezes were heard. The heart showed no abnormality although the heart sounds were distant. The abdomen was scaphoid and there was voluntary rigidity and tenderness over the upper abdomen. The liver was

felt three fingerbreadths below the costal margin but no other organs or masses were palpable. There were bilateral indirect inguinal herniae present and there was a small pilonidal cyst at the base of the spine. Rectal examination revealed the presence of internal and external hemorrhoids. The extremities showed sclerotic changes of the vessels.

Laboratory Data.—The urine showed a specific gravity of 1.020 and other tests were negative. The red blood count was 4,120,000, with 11 Gm. of hemoglobin. The white blood count was 13,000, with 70 per cent polymorphonuclears, 15 per cent lymphocytes, 11 per cent monocytes, 2 per cent eosinophiles, and 2 per cent stab forms. The blood nonprotein nitrogen was 32 mg. per cent; the albumin-globulin ratio, 3.8/2.9 Gm. per cent. The cephalin flocculation test was negative. The blood calcium was 9.6 mg. per cent; phosphorus ranged from 5.05 to 3.85 mg. per cent, and the acid phosphatase was 6.1 Bodansky units and the alkaline phosphatase, 9.4. The blood amylase was 9.8 units. A stool specimen for blood was 1 plus to the guaiac test. Examination of gastric contents revealed 4 plus occult blood with the benzidine test. Fasting contents showed 10° of free hydrochloric acid and 29° total acidity; one hour after the administration of histamine there were 8° of free hydrochloric acid and 17° total acidity.

Roentgenograms were reported as follows: A postero-anterior view of the chest disclosed a large parahilar mass on the left side. Examination of the gastrointestinal tract revealed the stomach to be normal. There was evidence of multiple ulcerations of the duodenal bulb and fixation of the loops of the second portion of the duodenum. On intravenous pyelography the lower pole of the right kidney was found to be 7.5 cm. below the iliac crest and the lower pole of the left kidney at the level of the fourth lumbar vertebra. There was very dilute concentration of the dye in the right ureter and renal pelvis and none on the left. There was no gross pathology of the lumbar spine.

Course.—The temperature and pulse remained normal except for slight terminal rise. During the twenty-five days of his hospitalization the patient showed rapidly progressive weakness and emaciation. He was ambulatory for the first two weeks and during that time complained

of the Duct.—The immediate results appear favorable, but the late results are poor because of return of the stricture. There are not many cases available for analysis.

- 4. Reconstruction of the Duct over a Tubethe Wilms-Sullivan Operation.—A tube is placed in the upper and lower ends of the duct and surrounded by omentum, connective tissue, or vein wall. The results are discouraging for the tract fibroses and constricts. Eliot4 reports 35 cases most of them failures.
- 5. Anastomosis of the Hepatic or Common Duct to the Stomach, Duodenum, or Jejunum.-This operation has two faults: (1) stricture at the anastomosis; (2) cholangeitis from ascending infection due to the lack of the sphincter of Oddi. Regarding this, Whipple<sup>5</sup> said, "The rare successes, not the many failures, appear in the literature." Allen<sup>6</sup> said, "One wishes to avoid, if possible, anastomosis between the duct and the gastrointestinal tract, since under these circumstances an ascending infection is so apt to occur." The results of Eliot's review4 show:

Hepatoduodenostomy: 41 cases; 11 cases well Choledochoduodenostomy: 27 cases; 5 cases well

These figures do not reflect the incidence of hepatoduodenostomy, for it is a not uncommon operation, and many cases go unreported. The results may be better with David's method2 of anastomosis.

- Transplantation of a Biliary Fistula.—This method was fairly popular ten years ago, but it is gradually being discarded. This view is stated by Leahy<sup>8</sup> as follows: "It is my opinion that the operation is bound to be followed by a good many failures as it is really a makeshift procedure."
- 7. Implantation of a Vitallium Tube.—In those cases with extensive loss of the duct or irreparable stricture, the author has permanently implanted a vitallium tube to take the place of

the duct or to hold open a strictured area. 9,10 This method has been widely used, but it is still too early to judge the permanent effect in a large series.

## Summary

1. Injury to the common bile duct occurs most frequently during cholecystectomy from: (a) insufficient exposure; (b) strong traction on the gallbladder which angulates the common duct so that it looks like a part of the cystic duct; (c) inflammation which shortens the cystic duct; (d) anatomic abnormalities which confuse the relations; and (e) blind efforts to control bleed-

Injury to the common duct may best be prevented by a careful dissection of the relation of the cystic, hepatic, and common ducts before anything is clamped or cut.

3. Injury is best repaired by immediate endto-end suture of the duct.

4. The late effect of injury is stricture. This can best be treated by excision and end-to-end anastomosis when the stricture is small. The stricture reforms if this is done when there is tension on the suture line. In extensive loss of the duct or long strictures the use of a permanently implanted vitallium tube has been helpful. Both of these procedures preserve the function of the sphincter of Oddi and help to prevent cholangeitis which so frequently follows anastomosis of the duct to the gastrointestinal tract.

# SOCIOLOGISTS SEE EFFECT OF MARRIAGE ON CRIME RATE

Among men and women 50 or more years old with an unbroken marriage there is a lower crime rate than among persons in the same age group who are single or divorced, it was reported at the convention of the American Sociological Society, which was held recently at the Hotel McAlpin in New York City.

Dr. Otto Pollak, of the University of Pennsylvania, who presented the report, pointed out, however, that this crime record does not apply to homicides. There, he said, the relation seems to be reversed. The middle-aged man who resorts to murder is usually married and his victim in

the majority of cases is either his wife or a female Relatively few women in this age group under relative.

take crime in any form, the sociologist reported. Dr. Robert Graham Caldwell, of the University of Delaware, reported that the available statistics indicate that neither the whipping post nor imprisonment effectively deterred those who have been so punished from again committing crimes. He cited as significant the fact that those who received the greatest amount of personal attention subsequently had the lowest rate of relapse into criminal

habits.

as we have here. I would like to add a fourth possibility—carcinoma of the body of the pancreas. This would not obstruct the biliary tract and would show itself as pressure on the prepvloric region or the greater curvature of the stomach. As to the mass in the hilar region, I would consider this as metastatic, not to the lung itself, but to the mediastinal nodes. Carcinoma of the body of the pancreas is my first choice. As far as the possibility of carcinoma appearing at the site of peptic ulcer is concerned, I have seen several such cases and, only recently, had a patient who died of generalized metastasis eighteen months after operation for typical peptic ulcer. Pathologic examination of the operative specimen showed typical small nests of carcinoma cells around the periphery. The Mayo Clinic group also has reported several cases of peptic ulcer degenerating into carcinoma.

Dr. Herman O. Mosenthal: The history in this case is of little help. The laboratory findings in the urine seem rather contradictory. It has been our experience that a negative pyeloram is of value in ruling out kidney disease, but abnormal findings on intravenous pyelography are frequently misleading. Pain in the back is consistent with the diagnosis of carcinoma of the body of the pancreas.

DR. HARRY A. SOLOMON: I would like to say that failure to obtain visualization of the dye on intravenous pyelography is frequently due to the administration of fluids before the x-rays are taken.

Dr. Max Trubek: All the laboratory data is contradictory. The clinical chest findings are not clear cut and do not mean anything. I would favor metastatic carcinoma to the mediastinum. I do not feel that carcinoma of the body of the pancreas is a possibility, for the patient usually has back pain at night also, loss of weight, often stool disturbances, and a mild diabetes. The amylase as recorded is normal and should be elevated without any extensive pancreatic destruction. There need not be icterus if the head is uninvolved. However, I believe that the primary lesion is in the prepyloric region of the stomach and that it is a carcinoma with metastases to the liver and lungs. There was no evidence to support tumor in the kidneys or prostate.

Dr. Zachary Sagal: Why was the diagnosis of duodenal ulcer made?

Dr. EMANUEL APPELBAUM: The long history of epigastric pain occurring after meals and relieved by alkalis, and the X-Ray Department's interpretation of the gastrointestinal series made me feel that we had to accept the existence of duodenal ulcer.

DR. CATHERINE R. KELLEY: For primary

carcinoma of the bronchus the course was too rapid. The mass seen on x-ray was primarily in the mediastinum rather than in the lungs and is a group of mediastinal glands. I would say that the patient had a carcinoma of the gastrointestinal tract. Dr. Appelbaum, what would you say was the cause of death?

DR. EMANUEL APPELBAUM: The patient died of progressive asthenia and emaciation, as most carcinoma patients die.

### Pathology

DR. ROBERT POPPITI: At necropsy, the body was that of a normally developed, poorly nourished 55-year-old white man with bilateral ankle edema. There was 1,000 cc. of clear ambercolored fluid within the peritoneal cavity. The inferior margin of the liver descended five cm. below the xiphoid process. There were no changes in the heart other than an atherosclerotic plaque at the base of the anterior leaflet of the mitral valve. A few atheromatous plaques were found on the internal surface of the aorta in the region of the bifurcation. The left lung was enlarged-it weighed 880 Gm. A few fibrous adhesions were found on the posterior surface of the upper lobe. Two cm. from the carina, the wall of the left main bronchus was markedly thickened, expanding into a mass measuring 4 cm. in diameter. The mass extended into the left upper lobe but did not ulcerate into the lumen of the bronchus. The cut section of the tumor was soft, gray, and necrotic. The tracheobronchial and hilar nodes on the left side were greatly enlarged, being filled with soft gray tumor tissue. The right lung was congested and edematous.

The liver was firm and enlarged—it weighed 2,500 Gm. Scattered throughout were numerous tumor nodules which varied from 2 mm. to 2 cm. in diameter. Several large tumor-filled lymph nodes were found in the hepatoduodenal ligament. The spleen, pancreas, and adrenals showed no noteworthy changes.

The left kidney was small and weighed 20 Gm. The left renal artery was hypoplastic and communicated with the aorta through a tiny orifice. The right kidney was large and weighed 350 Gm. Aside from the increased size, it showed nothing unusual.

The prostate was asymmetrically enlarged due to the presence of adenomata within the left lateral lobe.

In the duodenum, a short distance from the pylorus, was a small ulcer measuring 5 mm. in diameter. The underlying duodenal mucosa was thick and fibrosed. Several diverticuli were found in the sigmoid.

Microscopic examination revealed an oat-cell

frequently of pain in the back. The cough was never remarkable. On October 26 moist rales were noted in the right lung. These increased somewhat in the next few days and persisted. On November 6 a constant low-pitched wheeze in the left interscapular area was noted. Bronchoscopy was done and was reported as entirely negative. By November 5 the patient was quite apathetic and dehydrated. Oliguria was marked: the blood nonprotein nitrogen had risen to 64 mg. per cent and the urine concentration test showed specific gravity of 1.010. The white blood count at this time was 9,500. Daily infusions of glucose in saline with amino acids were started and one transfusion given, but the patient died on November 12 in a comatose state.

#### Discussion

DR. EMANUEL APPELBAUM: This is a very interesting though rather complicated case. It seems to me that there are two important questions to be answered. In the first place, we have to decide whether we are dealing with a single disease or with more than one clinical entity. Secondly, we have to determine whether or not the patient had a malignancy. This involves also a consideration of the sites of the primary lesion and of the metastasis. In addition, a few problems of lesser importance remain to be discussed.

The staff recognized at the outset the complex nature of this case and challenged me to make a diagnosis. When I first examined the patient I was impressed, mainly, with the abnormal physical signs at the base of the right lung, the tenderness in the epigastrium, and the enlargement of the liver. My diagnosis then was bronchogenic carcinoma with metastasis to the liver.

However, it soon became apparent that the case was not quite so simple. For one thing, the gastrointestinal roentgenogram was reported as showing multiple ulcerations of the duodenal This interpretation, however, was challenged by one observer, who regarded the gastroduodenal deformity as a carcinomatous defect. Another surprise finding was the left parahilar mass shown in the chest film. As you have heard, no distinct abnormal physical signs were found clinically over that area. The negative bronchoscopy further added to the con-

In the light of this rather confusing information it became difficult to establish a definite diagnosis. The following major interpretations were considered:

Carcinoma of the stomach with metastasis to the liver and mediastinal glands. One had

to reconcile this diagnosis with the patient's history, which was definitely suggestive of peptic ulcer. It could be assumed that the cancer was on an ulcer basis. In this connection, it may be noted that there is still a great deal of controversy as to the frequency with which gastric ulcer eventually becomes malignant. Investigators of the Mayo Clinic, notably Wilson and McCarty, are of the opinion that a high percentage of ulcers develop into cancer. On the other hand, many observers, including Ewing and Schindler, doubt completely the existence of cancer on an ulcer basis. It is generally accepted that gastric cancer may occur in 2 to 3 per cent of the ulcer cases. It must also be borne in mind that carcinoma of the stomach may begin with ulcer symptoms, without the presence of ulcer. With regard to metastasis, it may be noted that gastric carcinoma does not as a rule metastasize to the mediastinal glands but rather to the pulmonary lymphatics, producing carcinomatous lymphangitis.

2. The second interpretation was that the patient suffered from two disease entities, namely, a bronchogenic carcinoma with liver metastasis and a duodenal ulcer. However, if one assumed that the parahilar mass was at the site of the primary lesion, it was difficult to explain the negative bronchoscopy. It was, of course, possible that the primary carcinoma was located in a bronchus other than the one examined and the mass was composed of mediastinal

glands.

The third diagnosis was primary carcinoma of the liver with metastasis to the mediastinal glands. The duodenal ulceration was considered as an independent entity.

It was also suggested that the parahilar mass might be a benign neoplasm. This view, how-

ever, did not gain much support.

My own conclusion was that the patient suffered from two disease entities, namely, duodenal ulcer and bronchogenic carcinoma with metastasis to the liver and the mediastinal glands. I have already mentioned the possibility of the primary lesion being in a bronchus other than the one examined. The terminal rise in the blood nonprotein nitrogen was probably due to dehydration. I have no adequate explanation for the failure of the dye to appear in the pelvis of the left kidney.

DR. ZACHARY SAGAL: I think that the x-rays show definite prepyloric pathology with stasis of the second portion of the duodenum and obstruction of the third portion. This appears quite clearly. The X-Ray Department had the advantage of fluoroscopy, which might show that the prepyloric defect is due to spacm. Carcinoma will produce such an x-ray picture

## Special Article

### THE DIAGNOSIS AND TREATMENT OF PNEUMONIA

Recommendations by the Pneumonia Advisory Committee of the New York City Department of Health

THERE has recently been a large and increasing number of deaths from pneumonia in New York City in spite of the availability of the sulfonamide drugs. Because of this the Pneumonia Advisory Committee to the Department of Health has recommended the release of a statement to the medical profession calling attention to the necessity of early diagnosis and adequate treatment of pneumonia.

In New York City during the past month the number of deaths from primary pneumonia reported to the Department of Health has far exceeded the average number of deaths which would be expected during this period of the year. The number of reported deaths from primary pneumonia is larger than it has been for some years, and is particularly striking since it is occurring in an era when sulfonamide drugs are available. It is also high in comparison with deaths in pneumonia reported in many of the years of the pre-sulfonamide era. This increase was closely associated with the present outbreak of upper respiratory infections which may have contributed to the increase in the number of deaths.

The available evidence on cases of pneumonia in New York City during the present outbreak indicates that the etiology of such cases cannot be related to any particular micro-organism and that many different micro-organisms are involved. These include pneumococci of various types, the beta-hemolytic streptococcus, Staphylococcus areus, influenza bacillus, and Friedländer bacillus.

The intelligent management of the pneumonia patient requires that an etiologic diagnosis be established. It has been disappointing to note that since the advent of the sulfonamides there has been a gradually decreasing interest on the part of physicians in determining the bacterial etiology of pneumonia in their patients. The number of bacteriologic examinations of sputum performed by the Bureau of Laboratories of the New York City Department of Health has been insignificant in comparison with the number of reported deaths.

In considering the diagnosis and treatment of

\* These recommendations were considered timely by the New York City Pneumonia Advisory Commutee at a meeting on January 5, 1944. The wave of pneumonia was not confined to New York City. In New York State, excluding New York City, more deaths were reported in December, 1943, than in any other December on record, and most of the excess deaths were attributed to pneumonia.—Editor

pneumonia patients, the following points are stressed:

- 1. There are a number of symptoms occurring in pneumonia which should lead to a suspicion of the presence of that disease and which often help in determining the occurrence of pneumonia in a patient suffering from upper respiratory infection or influenza. These include:
  - (a) Shaking chill.
  - (b) Pleural pain.
  - (c) Rusty or bloody sputum.
  - (d) Continued high fever.
  - (e) Cyanosis.
  - (f) Rising pulse rate.
  - (g) Rising respiratory rate.
  - (h) Shortness of breath.
  - Persistence of fever accompanied by cough and expectoration.
  - (j) Recurrence of fever following apparent recovery from the initial respiratory disease.
- A knowledge of the bacterial etiology of the pneumonia is of great value in interpreting the course of the patient's disease, ascertaining reasons for failure of sulfonamide administration, indicating need for other types of therapy. and interpreting the occurrence of complications. It is desirable that a bacteriologic examination of the sputum, including pneumococcus typings and blood cultures, be performed in all cases of pneumonia as soon as diagnosis is made. Such bacteriologic examinations are an absolute necessity when patients do not respond favorably to 18-24 hours of adequate sulfonamide therapy. Delaying the bacteriologic examination while awaiting results of therapy increases the difficulty of ascertaining the etiologic agent.
- 3. The sulfonamide drugs which are most effective in the treatment of bacterial pneumonia are sulfadiazine, sulfathiazole, and sulfamerazine. An accepted dosage schedule for sulfadiazine and sulfathiazole consists of an initial dose by mouth of 4 Gm. followed by 1 Gm. every 4 hours until the symptoms have subsided and the temperature has been normal for 48 hours. In the case of sulfamerazine the schedule is similar except for a dosage of 1 Gm. every 6 to 8 hours instead of every 4 hours.

Where patients are seriously ill or in the presence of vomiting, it may be desirable to substitute for the initial oral dose an intravenous dose consisting of 5 Gm. of the sodium salt of

carcinoma of the left bronchus with secondary carcinoma in the hilar lymph nodes, liver, and spleen. Sections taken through the duodenal ulcer revealed rather deep penetration of the wall with a marked chronic inflammatory and fibroblastic response.

## Anatomic Diagnoses

Oat-cell carcinoma of the left main bronchus with secondary carcinoma in tracheobronchial lymph nodes, liver, and spleen. Pulmonary edema.

Chronic fibro-adhesive pleuritis, bilateral, Chronic fibro-adhesive pericarditis.

Atherosclerosis of aorta and mitral valve. Hypoplasia of left renal artery with atrophy of left kidney.

Hypertrophy of right kidney. Chronic duodenal ulcer. Diverticuli of sigmoid.

Ascites. Adenomatoid hyperplasia of prostate.

#### "HOMEMADE" PENICILLIN

To the Editor:

Since July, 1941, the Northern Regional Research Laboratory, which is one of four regional research laboratories operated by the Bureau of Agricultural and Industrial Chemistry, Agricultural Research Administration, U.S. Department of Agriculture, has been extensively engaged in research on the production of penicillin. This work has been broad in scope, including the isolation of many new penicillin-producing organisms, spore selection to secure higher producing strains, improvement of the culture mediums, and isolation and purification of the penicillin itself.

During recent weeks a number of scientific articles and press releases have appeared indicating that the production of penicillin preparations suitable for external use is a comparatively simple matter that can be undertaken in laboratories possessing only limited facilities, or even in the kitchen. The work thus reported, in some cases, may constitute noteworthy contributions to the field of penicillin therapy, and it is not our wish to minimize in any way the possible importance of these investigations. We do, however, feel that the time has come when a word of caution should be given. Statements to the effect that Penicillium notatum is the green or blue-green mold found on bread, cheese, or other foods are quite misleading if, in fact, not actually dangerous. This species does often occur on these products, but so do a great variety of other bluegreen molds. In the genus Penicillium there are literally scores of blue-green species which can be distinguished from P. notatum and its allies only by painstaking laboratory cultivation and microscopic examination. This fact is illustrated by our work of recent months. We have made a concentrated effort to isolate as many strains as possible of P. notatum, P. chrysogenum, and other closely related species and have examined hundreds of samples of molded foods, fruits, soils, and other possible sources of material. We consider it a conservative estimate that not one out of fifty of the blue-green molds encountered belonged to the P. notatum group. Not more than one out of one hundred represented the species P. notatum itself, and only a limited number of these produced appreciable yields of penicillin.

The metabolic products of only a few of the other blue-green species of molds have been adequately studied, and it is entirely possible that among them exist some species or strains that are capable of producing, in considerable quantity, substances as toxic to animals as to certain pathogens which infect them. A number of blue-green molds, such as P.

citrinum, P. spinulosum, P. puberulum, P. aurantiovirens, Aspergillus clavatus, A. fumigatus, and Gliocladium fimbriatum, are already known to produce bactericidal substances, some of which are quite toxic when injected into laboratory animals. One therefore should be extremely careful in the selection and maintenance of cultures for use in the production of penicillin.

Contamination of P. notatum cultures with other blue-green species or with pathogenic organisms is also a matter of serious concern. This is emphasized by the fact that, in certain recent cases, experienced workers have started with a good penicillin-producing culture and subsequently found this to have become contaminated or even replaced by

an entirely different species or strain. In the hands of inexperienced workers, or in laboratories

with inadequate facilities, this possibility is multiplied many times. If a contaminating organism should produce some material toxic to man, the dangers involved might be very considerable. In the present state of our knowledge of the metabolic products of the blue-green Penicillia and Aspergillias a whole, the indiscriminate selection of newly isolated cultures for penicillin production should not even be considered until their correct identity is established.

Owing to the pressure of other work, the staff of this laboratory is not in a position to check the

correctness of all cultures which may be used in this type of experimentation. We have, however, deposited with the American Type Culture Collection, 3900 Reservoir Road, Washington, D.C., cultures of the two strains of P. notatum which are being used almost universally in industry for the production of penicillin, and these are available on request

for a nominal charge.

Another possibility which must be considered when using these crude forms of penicillin is that the patient may conceivably become sensitized to mold protein, which is inevitably present in such preparations. The danger of this would be particularly great when these protein-containing solutions are applied to an extensive burned area. Commercial preparations of penicillin are protein free and have been thoroughly tested for bactericidal activity, progens, toxicity, and sterility.

activity, pyrogens, toxicity, and sterility.

In summary, we feel that there is inherent danger in the proposed practice of using "homemade" penicillin, for the reasons outlined.—Letter in the J.A.M.A. signed by Kenneth B. Raper, Ph.D., and Robert D. Coghill, Ph.D., senior microbiologist and chief, respectively, of the Peoria, Ill., Fermentation Division, Northern Regional Research Laboratory

#### A FRIENDLY GESTURE

A recent announcement which should prove of interest to American obstetricians and gynecologists comes from England. It relates to the endowment of a lectureship by an anonymous donor, a Fellow of the Royal College of Obstetricians and Gynecolo-The interest from a fund of one thousand guineas is to be devoted to a lecture every second year alternately by a member of the Royal College on the subject of infertility and by an obstetrician or gynecologist from the United States on any topic selected by him. This would mean that an invitation to a American to the control of t tion to an American participant would be possible every fourth year and the honorarium would amount to about seventy pounds or the equivalent of some three hundred dollars.

The Royal College of Obstetricians and Gynecologists was founded in 1929 by W. Blair-Bell of Liverpool, who was its first president, with William Fletcher Shaw of Manchester as secretary. The latter, after having served as president for the past five years and being knighted, is now retiring from

office and is being succeeded by Eardley Holland of London. The endowed lectureship commemorates Sir William Shaw's presidency and the anonymous donor wishes to demonstrate and further the friendship felt by our English colleagues toward the American profession. As such, it is worthy of our gratitude and appreciation. The postwar period, with means of communication fully restored, should witness the development of closer bonds between the great English-speaking countries. The interchange of ideas through the medium of personal contacts between groups interested in special branches of medicine can accomplish much, not only among the participants, but among those whom they serve in a professional capacity. It is to be hoped that these objects may be possible of execution at an early date when the specter of war has been eliminated and opportunity offered again for more peaceful pursuits.—From January, 1944, issue of the American Journal of Obstetrics and Gynecology

sulfadiazine or sulfathiazole or 4 Gm. of sodium sulfamerazine dissolved in a liter of physiologic saline solution, or in a 5 per cent solution in sterile distilled water. Solutions of these drugs in physiologic saline solution may be given subcutaneously in concentrations of 1 per cent or less.

Sulfonamide administration should be accompanied by an adequate fluid intake (3,000-4,000 ml. in an adult) and by the use of alkali sufficient to maintain an alkaline reaction of the urine. 6 Gm. (90 grains) of sodium bicarbonate as an initial dose and 2.5 Gm. (40 grains) of sodium bicarbonate every 4 hours has been recommended as the dosage for adults except when nephritis or other contraindicating disease is present). The primary purpose of such therapy is to maintain a urinary output of at least 1,200-1,500 ml. per day.

Great caution must be exercised in the administration of fluids to patients with heart disease or to those who have evidence of congestive cardiac failure. The administration of fluid in these patients must be guided by the urinary output. Fluid administration in such patients should be limited to the minimum amount which will assure such urinary output.

The use of sulfonamide drugs in the treatment of simple upper respiratory infections is undesirable. When the severity of an upper respiratory infection is an indication for sulfonamide administration, investigation for the presence of pneumonia or other complicating disease should be instituted and the drug should be given in therapeutic amounts similar to the schedule indicated above. Small doses of sulfonamides over long intervals may produce drug-fast strains of micro-organisms, and may sensitize the patient to the drug. Therefore, small doses of sulfonamides over long intervals are to be avoided.

Patients receiving sulfonamide drugs should be watched for the occurrence of symptoms due to the toxic action of the sulfonamides. These include:

- (a) Hematuria, oliguria, anuria, and flank pain.
- (b) Skin rashes.
- (c) Drug fever.
- (d) Extreme nausea or vomiting.
- (e) Agranulocytosis.

With the exception of (a), these symptoms usually do not appear until the patient has been receiving the drug for about a week. If sensitivity to one drug becomes apparent, another should be substituted, although sulfamerazine and sulfadiazine should not be substituted for each other.

4. When a patient has been receiving adequate sulfonamide therapy in accordance with a schedule similar to that in paragraph 3 and does

not respond to such medication within 18-24 hours. the patient should be re-evaluated. Such reevaluation should include a complete physical examination to determine the status of the pneumonia, the presence of complications of the disease and of toxic reactions to sulfonamides, determination of the level of sulfonamide drugs in the blood, and an evaluation of the bacterlologic findings in the sputum and blood. If such re-evaluation indicates that the continued course of the patient's disease is due to pneumonia, and if the sulfonamide level in the blood is low, additional amounts of drug should be given. If the sulfonamide blood level is adequate (5-10 mg. per cent of free drug in the case of sulfadiazine and sulfamerazine and over 3 mg. per cent in the case of sulfathiazole) and if a type-specific pneumococcus (particularly of the common type) has been obtained from the sputum, or if a typespecific pneumococcus has been obtained from the blood culture, type-specific antipneumococcus serum therapy should be begun immediately. Such therapy should be preceded by the taking of a history of allergy and the performance of a skin and a conjunctival sensitivity test. At least 100,000-200,000 units of serum should be administered within 6 hours from the time when serum administration is begun.

5. The availability of specific therapy for pneumonia has not decreased the importance of careful, repeated physical examinations of the patient and the many nonspecific measures which assist the patient in combatting his disease. These include adequate nursing care, provision of complete rest, oxygen therapy, maintenance of fluid balance and the treatment of pleural pain with codeine. Such treatment is best administered in a hospital, particularly in the light of the present shortage of nurses. It is recommended that all cases of pneumonia be hospitalized early if hospital facilities are available. It is extremely important that all severe cases be hospitalized.

6. Patients who have had pneumonia for more than a few days and have not responded to adequate treatment should be suspected of having developed complications of the disease.

The most important of these is empyema, the diagnosis of which is facilitated by an x-ray examination of the chest, as is the spread of pneumonia to previously uninvolved portions of the lungs. Other complications include otitis media, thrombophlebitis, endocarditis, and meningitis. The early diagnosis of empyema and its proper treatment may be life-saving.\*

Cecil, Maxwell Finland, Frank Horsfall, Colin M. MacLeod, James W. Jobling, E. H. Loughlin, James E. Perkins, Director, W. Tillet, and I. Ogden Woodruff.

## Medical News

#### American Medical Association to Hold Annual Session in 1944

A NNOUNCEMENT has been made officially that the American Medical Association will hold its 1944 annual session June 12-16 in Chicago. The House of Delegates will meet in the Palmer House, where the Scientific Exhibit and the Opening General Meeting will also be held. The Registration Bureau and the Technical Exhibits will be in the Hotel Stevens, and the meetings of the various sections will be assigned to these hotels and, in addition, to the Hotel Sherman and the Morrison Hotel.

A prospective feature of the annual session is a national medical war meeting at which there will be present distinguished representatives of the medical military services of the United Nations as well as other eminent speakers. The program and the place of this and other meetings will be announced as

plans are completed.

At the Conference of Section Secretaries with the Council on Scientific Assembly held in the headquarters of the American Medical Association in December, consideration was given particularly to salient features of the scientific programs. Plans were made for many round-table and panel discussions and for symposiums on subjects of current interest, including such topics as the amino acids and the vitamins in nutrition, the dysenteries, postwar trends in obstetrics, industrial ophthalmology, new advances relating to the uses of penicillin and the sulfonamides, head injuries, asphyxia, the neuroses, fatigue, nutrition and rehabilitation, new aspects of endocrinology and urology, malaria and other tropical diseases, blood transfusion, and new advances with blood and blood substitutes. A special section will be devoted to the interests of the general practitioner, and section officers have been appointed to work out a program designed particularly for this group. Already the applications for places on the program are sufficient to indicate the usual assembling of scientific discussions enhanced by new methods of presentation and exhibition.

Since the transportation and hotel facilities of Chicago are likely to be taxed to the utmost under war conditions, those who plan to attend the annual session should make the necessary reservations just as soon as the official announcement appears in the Organization Section of the Journal and in the advertising pages in the near future.—J.A.M.A.

#### W.M.C. Releases Opinion on Waivers for Physical Defects

WHAT are the implications of waivers for known physical defects which physicians sign upon being appointed for limited service in the Army Medical

Corps?

The answer to this recurrent question is clarified in a recent opinion on the subject made by the Office of the Judge Advocate General of the Army. opinion, released by the Procurement and Assignment Service of the War Manpower Commission, is as follows:

"Response is made to your oral inquiry whether acknowledgment, on the accompanying form, of existing physical defects would preclude a person from thereafter claiming benefits to which he would otherwise be entitled on account of the service connected aggravation of such defects. As to the defects acknowledged, the execution of such an instrument merely provides additional evidence of their existence, and to that extent would operate to preclude the person involved from thereafter claiming benefits on account of them. It is the opinion of this office, however, that the mentioned form does not purport to be a waiver of possible future benefits to which the individual might become entitled by reason of any service-connected aggravation of such defects, and would not operate to deprive the individual of any possible benefits on account of such aggravation."

#### Welfare Council Sponsors Open Information Meeting

NEW York City has ample facilities for the treatment of venereally diseased and tuberculous servicemen and Selective Service rejectees, but needs more centers and clinics for men discharged or rejected for psychiatric reasons, leaders and workers in the social service field were told on Wednesday, January 12, at an open information meeting sponsored by the Committee on Information Services of the Welfare Council of New York City at Theodore Roosevelt House in New York City. Four physicians and public health experts directly concerned with the treatment of servicemen and rejectees addressed the meeting.

"The program in New York City for the medical care of venereally infected servicemen is well rounded and all-inclusive," Dr. Theodore Rosenthal, Director of the Bureau of Social Hygiene of the Department of Health, said. "It takes into consideration not cally the infeated individual his sources and tion not only the infected individual, his sources and contacts, but also the necessary public health control machinery." Dr. Rosenthal, who is a special consultant of the United States Public Health Service, said that cooperative relationships for the referral and transfer of venereally infected soldiers and sailors from their military units, on discharge from service, to the civilian community are already in effect and "are working out satisfactorily."

"The Department of Health has for some years had trained workers stationed at the induction center to interview all registrants rejected because of venereal infection," Dr. Rosenthal said. "These men are immediately referred for appropriate treatment to private physicians or to the nearest clinic." In addition, he pointed out, information as to source of infection and contact is obtained and in due course transmitted to the proper civilian authority.

"The introduction of newer and better remedies for the treatment of venereal infection offers great hope," Dr. Rosenthal declared. "The development of rapid, intensive methods of syphilotherapy with the standard arsenical drugs, and more recently the use of penicillin, have been milestones of progress. In gonorrhea, the introduction of sulfa drugs, as well as penicillin, has likewise constituted an advance of the first importance."

Practically all of the men rejected by Selective

## Postgraduate Medical Education

Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York are published in this section of the JOURNAL. The members of the committee are Oliver W. H. Mitchell, M.D., Chairman (428 Greenwood Place, Syracuse); George Baehr, M.D., and Charles D. Post, M.D.

### Lecture on General Medicine at St. Lawrence and Jefferson Counties

POSTGRADUATE instruction in general medicine was given to the Jefferson County Medical Society on Thursday, February 10, at 6:30 P.M., at the Black River Valley Club in Watertown. A lecture, "Interpretation of Gastrointestinal Symptoms," was delivered by Dr. Albert F. R. Andresen,

professor of clinical medicine at Long Island College of Medicine, Brooklyn.

The St. Lawrence County Medical Society heard the same lecture by Dr. Andresen at 12:00 M. on February 10, at the Potsdam Club, Potsdam,

## General Medicine to Be Topic of Tompkins County Lectures

HREE lectures in general medicine will be given before the Tompkins County Medical Society on Tuesday evenings at 8:30 P.M., at the Tompkins County Memorial Hospital, Ithaca, New York. The first is "The Management of Arthritis, Acute and Chronic," given by Dr. L. Maxwell Lockie, professor of therapeutics and head of the department at the University of Buffalo School of Medicine on February 15.

On April 18 Dr. Byron D. Bowen, associate professor of medicine at the University of Buffalo School of Medicine will deliver a lecture entitled "The Management of Diabetes with the Newer Forms of Insulin."

"Evaluation of the Common Drugs Used in General Practice" is the lecture to be given on May 16 by Dr. A. H. Aaron, professor of clinical medicine at the University of Buffalo School of Medicine.

#### "DOCTOR JONES" SAYS-

Well, it's getting along time for the legislature to meet again and I hear the chiropractors are marshalling their forces: going to make another try at getting a law passed to license 'em. Of course I'm just a doctor and I'm s'posed to be prejudiced-and I am. It ain't their methods-adjusting supposedly misplaced vertebra and all that, although there's nothing to it but what any doctor could use if he was inclined that way. But I'm prejudiced against allowing folks to monkey with human diseases and ailments that aren't qualified by education and training to make a diagnosis and know what they're dealing with. I don't want anybody fixing my car or plumbing that don't know what's the matter. And I certainly value my life and health more'n I do my automobile or water pipes-even

As near as I can find out they didn't have to have any education to speak of to get into these chiro-practic schools—most of 'em that're practicing now. And I understand their courses usually run from eighteen months to three years. In that time they couldn't learn what you have to know to make difficult diagnoses, to say nothing of treatment. couldn't, not even with the education to understand it and real scientists to teach 'em and well-equipped

hospitals to work in.

Why, look at the veterinarians! They have to have a year of college work in basic sciences before they can get into the veterinary school. Then they have a four-year course that's tough. When they get their license their practice is limited to animals. I don't s'nose they'll account is limited to animals. don't s'pose they'll ever ask to be allowed to practice on humans but I'll bet if they did they'd be turned down flatter'n an off-day sponge cake. But with their educational background and thorough study of the medical sciences I figure they'd be safer'n most of these chiropractors.

I know there's always plenty of intelligent people ready to testify that they've been helped by these fellows. I don't question but what they have. But that don't prove their competence. Time and Nature have cured folks the doctors couldn't cure at the time. A lot of 'em were "cured," at least temporarily, by reciting Professor Coue's formula: "Every day and in every way I'm getting better and better." Any kind of a fancy manipulation will give relief in some cases. But the ones that had infections and so on that were made were by their infections and so on that were made worse by their treatment—you don't hear about them. Yes, sir-I knew a fellow that had a broken hip that wouldn't unite that was cured by falling downstairs. But I wouldn't advocate basing a new system of treatment on it. - Paul B. Brooks, M.D., in Health News

## PRIZE FOR RESEARCH IN HUMAN FERTILITY

An award of \$500 will be given in 1944 to the scientist who has made the most significant contribution to research in human fertility—either in the control of conception or the correction of sterility, Dr. J. H. J. Upham, president of the Planned Parenthood Federation of America, Inc., has announced.

Any scientist anywhere in the world may be

eligible for the award. In addition, a number of

plaques will be granted to others who have done important work in the field. The award will be made by the medical committee of the Federa-tion

The first award, a gift of Mrs. Albert D. Lasker, will be known as the Mary Woodward Lasker Prize. The closing date for submission of entries for the

awards is June 1, 1944.

and assistant director of the New York Tuberculosis and Health Association.

Elected to membership in the Tuberculosis Sanatorium Conference were: Dr. John F. Crane and Dr. S. L. Friedman, both of Montesiore Hospital, New York City; Dr. A. Joseph Hughes, director, Tuberculosis Division, New Jersey State Department of Health, Trenton, New Jersey; Dr. Max Kaplan, physician-in-charge, Red Hook Gowanus Health District Tuberculosis Service and assistant in preventive medicine and community health, Long Island College of Medicine; and Dr. Thamara M. Stander, Nassau County Department of Health. Mineola, New York.

#### County News

Albany County

A talk on "Penicillin-Its Background and Therapeutic Uses" was given before the country society at its meeting on January 26. Dr. Charles Frederick Church, of New York City, formerly senior medical officer of the Federal Trade Commission, was the speaker. The discussion was opened by Drs. Raymond F. Kircher, Arthur M. Dickinson,

and William Milner, all of Albany.

Dr. J. B. Horner, president of the county society, has announced the appointment of the following committee chairmen for 1944: woman's auxiliary advisory committee, Dr. E. W. Wilkins; economics, Dr. J. W. Bucci; public and press relations, Dr. W. C. Rausch; maternal welfare, Dr. J.O'C. Kiernan; cancer, Dr. I. J. Murnane; group hospitalization, Dr. K. E. Crounse; industrial health, Dr. W. P. Howard; program, Dr. J. J. Clemmer; public health, Dr. R. J. Erickson; legislation, Dr. O. A. Brenenstuhl; workmen's compensation, Dr. A. M. Dickinson, and war participation, Dr. S. E. Alder-

The following excerpts are from a story which appeared in the Albany Times Union of January 16:

The fight for disabled American veterans, now reaching peak intensity over the country, opened privately in Albany more than twenty years ago through the vigor of a slender, still erect gentleman of 72, Dr. H. Judson Lipes.

Known to thousands of Albanians for his distinguished career as an Army surgeon, Dr. Lipes is recognized by relatively few as one of the first to understand the social and medical problems of returning veterans—and to do something to solve them.

His many medals, now plush-boxed, flash history from the Mexican border to the fields of France; Aisne-Marne, St. Mihiel, the Meuse-Argonne. Pinned against the flush are the Purple Heart, the Silver Star for bravery, and the medal from New York State for conspicuous service.

But sole indication of his two-decade fight for veterans' aid is the commendation from Disabled American Veterans, albany Chapter No. 10, for his recent chairmanship of Forget-Me-Not Day.

Every day, however, has been Forget-Me-Not Day with Dr. Lipes. A ceaseless stream of veterans seeking funds and medical care passes daily through his office. The veterans get funds from the Disabled American Veterans. They get free medical attention from him. Their number is now increasing, their needs even more pressing, says Dr. Lipes.

Created in 1921 "of, by, and for wounded and disabled American veterans of all wars," the Albany chapter has been supported largely through the teamed efforts of Dr. Lipes and his secretary. It has worked as a private philanthropy backed by no War Chest or official organization. Resting entirely upon private contributions made annually to it by generous citizens, the group functions with no red tape nor application complications.

"All the veterans need say to us is that they need our help," developed Dr. Lipes.

October marked theur most successful campaign. "Success was due," said Dr. Lipes, "to the remarkably able assistance of the Junior Red Cross. Through the 130 grils who solicited for us on Forget-Me-Not Day, we realized several times more than we ever had previously. That money is now waiting for any veteran who needs it. Each day brings disbursements to someone.

"People don't recognize the uphill fight veterans have when

ments to someone.

"People don't recognize the uphill fight veterans have when they return home. They critically need someone's help. That's why we have had to build and maintain our Disabled American Veterans.

"The men and women coming back must be provided with some sort of wage that will feed them until they get well, if they've been injured, or tide them over until they manage

"This is what we fought for after the last war. This is what we are now fighting for again."

#### Broome County

Capt. Frank D. Conole, of Binghamton, officer in charge of the medical detail on a Liberty Ship, recently removed a soldier's appendix in an emergency operation aboard the ship in seas so rough that a chair was hurled across the floor of the small dis-pensary during the operation. The incident is re-ported in a story datelined "Somewhere in North Africa," in the December 31 issue of Yank.

Stricken while the Africa-bound vessel was six days out of an eastern United States port, Private Herbert Dewey, of Adrian, Michigan, was given preoperative injections of morphine and atropine and. in spite of the rocking motion of the ship, Captain

Conole performed the operation.

Twelve days after the operation the stitches were removed. A snug-fitting "corset," hand-stitched from sail-canvas by a member of the crew, was donned for abdominal comfort when Private Dewey was allowed out of bed. When the boat docked he walked down the gangplank under his own power.

Captain Conole\* was assisted in the operation by Maj. Rowland Rushmore, of Clinton, Iowa, veter-inarian, and Capt. Walter H. Kwiecten, of Bloom-

field, New Jersey, dental officer.\*

That the passage of the Wagner-Murray Senate bill 1161, calling for socialized medicine, would lay the "foundation for a bureaucracy of fantastic proportions" was the opinion expressed by Dr. H. I. Johnston, former chairman of the legislative committee of the Broome County Medical Society, at a meeting of the Quota Club held in Binghamton on January 12.

"Socialized Medicine" was the topic discussed by Dr. Johnston and Dr. George C. Vogt, present legislative chairman of the society. Dr. Johnston reviewed accomplishments of the medical profession in the last thirty years and said that much was due to individual initiative. In describing the attempts made in Germany, England, and New Zealand to bring the medical profession under government domination, he said that many doctors had refused to cooperate with the plan and that the result was detrimental.

Dr. Vogt said that the public would be the loser if the bill becomes a law because the tax burden would be greater. He also said that the medical profession recognizes the need for a medical indemnity plan for persons whose salaries are not adequate to cover

medical needs.

He said a plan could be worked out if the public could be given a clear understanding of what such legislation as the Wagner-Murray bill would mean. He also said that federal control of medicine would provide a "happy hunting ground" for political job seekers. He contended informed public opinion

<sup>\*</sup> Asterisk indicates that item is from a local newspaper.

Service for tuberculosis and other chest diseases are seen by the Department of Health within a short period after their rejection, Dr. Herbert R. Edwards, Director of the Bureau of Tuberculosis of the Health Department, declared. Approximately one per cent of all the men examined for Selective Service in this area have been found to have lesions characteristic of pulmonary tuberculosis and to be in need of some form of supervision. Through this kind of referral it has been possible to examine many additional thousands of persons who have been in contact with the infected men and may likewise have been infected.

"Perhaps one of the most important findings as a result of this procedure has been the number of cases with healed tuberculosis," Dr. Edwards said.

The experience of the Department of Health with the induction center underscores the importance of mass surveys of industrial workers and all pre-

employment groups, he added.

In discussing "Psychiatric Rehabilitation of the Discharged Service Man," Dr. Thomas A. C. Rennie, assistant professor of psychiatry at Cornell University Medical College, indicated that in New York City 90,000 men had been rejected for psychiatric disabilities and 20,000 men had been discharged for the same reasons. "The problem in the country at large is staggering and is steadily growing," Dr. Rennie said. "With 70,000 men being discharged each month from the armed services, onethird or approximately 25,000 are likely to be psychiatric disabilities."

The results obtained from psychiatric treatment of such men are encouraging, Dr. Rennie said, and "indicate the need for establishment of psychiatric centers or clinics for men of this group where they may secure help."

Reporting on the work of the Rehabilitation Clinic of the New York Hospital, which opened August 19, 1943, Dr. Rennie said that 150 men, most of them discharged from the armed services, had been registered. They represent a cross section of psychiatric disorders ranging from acute schizophrenic illnesses and depressions to psychoneuroses. The majority fall into the latter group, he indicated,

anxiety neuroses being most common. "The results of treatment have been most en-couraging," Dr. Rennie declared. "More than half these men show definite improvement. Many have recovered entirely. The treatment period is far briefer than that required for the ordinary civilian neurotic. With help, many of these acute conditions subside rapidly. Sometimes a single interview is sufficient to orient a man so that he accomplishes his recovery spontaneously."

The fourth speaker, Dr. Raymond S. Roy, of the Orthopaedic Service of the United States Marine Hospital at Staten Island, discussed "Physical Re-construction in Wartime Surgery." He substituted for Dr. Arthur A. Michele, Chief of the Orthopaedic

Service, who was ill.

Dr. Roy's talk was illustrated by lantern slides.

Seventh Postgraduate Course in Ocular Surgery, Pathology, and Orthoptics

THE George Washington University School of Medicine in Washington, D.C., has announced the seventh annual postgraduate course in ocular surgery, pathology, and orthoptics, which is to be held from Monday, April 24, to Saturday, April 29,

1944, inclusive.

The course in pathology embraces the normal histology of the eye, inflammations, general and specific, phthisis bulbi, glaucoma, cataract, arteriosclerosis, albuminuric retinitis, and intraocular and epibulbar tumors. The instructors are Col. J. E. Ash, (MC), AUS., curator of the Army Medical Museum, Maj. Alfred Golden, (MC), AUS., Helenor Wilder, and Lawrence Ambrogi. It will take place at the Army Medical Museum, 9:00 a.m. to 12:00 m. Monday through Friday, April 24-28, 1944. Transportation to the museum has been arranged.

The orthoptics course covers practical orthoptics, with case demonstrations. The instructors are Dr. William Thornwall Davis, Dr. Ernest Sheppard, Dr. Frank D. Costenbader, Louisa Wells, Mary E. Kramer, Dorothy R. Bair, and Mildred Brown. The meeting place is the George Washington United States of the Coordinate o versity School of Medicine; the time is from 1:15 to 3:15 P.M. Monday through Friday, and Saturday

morning from 9:00 A.M. to 12:00 M.

This course will be completed Saturday noon.

The pathology and surgery courses will be completed on Friday afternoon. As heretofore, the interesting and valuable round-table discussion on surgery and orthoptics will be held at 11:15 A.M. on Saturday,

April 29.

In the surgery course the registrants will operate on animal eyes under the direction of the instruc-tors, Dr. W. T. Davis, Dr. Ernest Sheppard, Dr. E. Leonard Goodman, Dr. Ronald A. Cox, Dr. Sterling Bockoven, Dr. Richard W. Wilkinson, and Dr. C. R. Naples. The following operations will be performed: combined intracapsular cataract ex-trection. Ellipt's salargament traphine, evolodialytraction, Elliot's sclerocorneal trephine, cyclodialysis, LaGrange, iridectomy, iridotasis, iridencleisis, Jameson resection, Reese resection, Worth advancement, and O'Connor cinch. The instruction will be held at the George Washington University School of Medicine from 3:20 to 5:30 P.M. Monday through Friday, April 24 through April 28.

The registration will be held at the School of Medicine, 1335 H Street, Northwest, on Monday, April 24, from 7:45 to 8:30 A.M. The Washington Hotel has reserved rooms for the registrants; make

your registration early.

For further information apply to the secretary, Miss Louisa Wells, 927 17th Street, N.W., Washington, D.C.

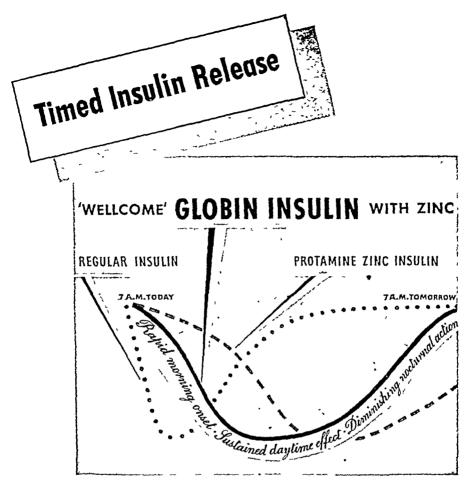

### Tuberculosis Conference Re-Elects Runnells

DR. JOHN E. RUNNELLS, superintendent and medical director of Bonnie Burn Sanatorium, medical director of Bonnie Burn Sanatorium, Scotch Plains, New Jersey, and consultant of Elizabeth General Hospital, Elizabeth, New Jersey, and Muhlenberg Hospital, Plainfield, New Jersey, was re-elected chairman of the Tuberculosis Sanatorium Conference of Metropolitan New York at its annual meeting held on February 2 at the Hotel Pennsylvania in New York City, in conjunction with the Annual Conference of the New York Tuberculosis

and Health Association.

Dr. James C. Walsh, medical director and superintendent, Nassau County Sanatorium, Farming-dale, L.I., was re-elected vice-chairman.

Also re-elected as secretary and consulting statistician of the conference, respectively, were Bernard S. Coleman, secretary of the Tubercu-losis Division, and Godias J. Drolet, statistician

A schematic representation of the effects of various insulins on the blood sugar of a fasting diabetic.

• 'Wellcome' Globin Insulin with Zinc, a new type of insulin, provides more efficient timing of action. Its rate of insulin release is such that its prompt effect meets the morning requirements; strong prolonged daytime action coincides with the period of peak need; and diminishing action during the night minimizes the possibility of nocturnal insulin reactions.

'Wellcome' Globin Insulin with Zinc conforms to the needs of the patient. A single injection daily has been found to control satisfactorily many moderately severe and severe cases of diabetes.

'Wellcome' Globin Insulin with Zinc, a clear solution, is comparable to regular insulin in its freedom from allergenic skin reactions.

'Wellcome' Globin Insulin with Zinc was developed in the Wellcome Research Laboratories, Tuckahoe, New York. Registered U. S. Patent Office, No. 2,161,198. Available in vials of 10 cc., 80 units in 1 cc. 'Wellcome' Trademark Registered

Literature on request

could mold a sensible and workable medical indemnity plan.\*

#### Chemung County

Appointment of Dr. William R. Phillips, of Elmira, as chairman of the Chemung County War ('ouncil's emergency medical service has been announced. He succeeds Dr. George R. Murphy and Dr. Earl D. Smith, who have resigned as cochair-

Dr. Phillips assisted Drs. Murphy and Smith for several months.\*

#### Erie County

A clinical meeting for physicians, as part of the Social Hygiene Week activities, arranged through the joint sponsorship of the Buffalo Syphilis Control Service and the Medical Society of the County of Erie, was held on February 3 at City Hall in Buffalo.

The program included a demonstration of U.S.P. II. S. Kodachrome slides on venereal disease lesions, with Dr. Earl D. Osborne as commentator; a demonstration of models of venereal disease lesions, prepared by Dr. Charles Bethune; and a presentation of current problems in venereal disease control by Dr. I. Jay Brightman.

#### Franklin County

Dr. Percival F. Dalphin, 76, dean of Malone physicians, completed fifty years of practice in Malone on January 3. He is in good health and is assisting in the third war during his lifetime. He is a veteran of the Spanish-American War and served for several months in the South in World War I.

Although unable to enter active military service in this war, he is relieving younger physicians by carrying on a busy practice in Malone and the sur-

rounding territory.

Dr. Dalphin was born in Richfield and received his degree at the Bellevue Hospital Medical College March 30, 1891. In November, 1891, he started a practice in Trout River, serving the small town and the large farming community on both sides of the international border. He went to Malone in 1894.\*

#### Jefferson County

The publication of a bulletin has been initiated by the county society. It will contain articles published or prepared by members of the society and will incorporate various departments, such as hobbies, letters from the men in service, case histories, propaganda for the furtherance of medicine, and medical relations.

Those interested in submitting original articles or material which could be used in one of the departments should communicate with Dr. Charles A. Prudhon, secretary, and submit the material before

April 1.

The regular monthly meeting of the county society was held on January 13 at the Black River Valley Club in Watertown. Following dinner at 6:30, Dr. S. E. Simpson, superintendent of the Jefferson County Sanatorium, discussed "Interesting Problems in Chest Diseases."\*

#### Kings County

The county society and the Academy of Medicine of Brooklyn held a stated meeting on the evening of January 18 in MacNaughton Auditorium, at which time the members heard two addresses. Dr. Lee S.

Schwartz, president, delivered his inaugural address, entitled "The Doctor and His Future." "The Postwar Malaria Problem in the United States" was discussed by Dr. Isadore Snapper, former professor of internal medicine at the University of Amsterdam, Holland, and professor and chief of the department of medicine at Peiping Medical College, Peiping, China.

A medal and scroll were presented to the retiring

president, Dr. John J. Gainey.

Conferences on obstetrics, sponsored by the Committee on Maternal Welfare, will continue through May. They are held at 4:30 P.M. in MacNaughton Auditorium on the fourth Tuesday of each month.

Approval of medical and health insurance plans asteps to "increase the efficiency" of medicine was indicated by Dr. Jean Alonzo Curran, president and dean of the Long Island College of Medicine, in an address at the college's eighty-fifth annual commencement held on December 30 in the Academy of Music.

Speaking before 91 graduates, 45 of whom received commissions as second lieutenants in the medical corps, Dr. Curran said that "the trend to place the resources of a group at the disposal of the individual patient" gives much promise of increasing the efficiency of the profession.

"The present growing interest in plans for pre-payment of medical care," he said, "will doubtless encourage more group practice and thus better cooperation in the use of medical resources."

Following Dr. Curran, the traditional commencement address was given by the Right Rev. J. I. Blair Larned, Suffragan Bishop of the Protestant Philosoppel Philosop Episcopal Diocese of Long Island. Rabbi Sidney S. Tedesche of Union Temple gave the benediction and the invocation and Dr. H. Sheridan Baketel, emeritus professor of preventive medicine, adminitered the Hippocratic oath.

Capt. Robert J. Geis, commandant of the college A.S.T.P, unit, presented the commissions to the army doctors and administered the oath of office. Capt. John K. Richards, commanding officer of the USNR Midshipmen's School, presented commissions to 24 navy trainees. Eight of the graduates

Dr. Curran also announced twelve faculty promotions and two new appointments. They are Dr. Howard W Potter to professor of clinical psychiatry. Dr. Edwig P. Morround to professor of clinical try, Dr. Edwin P. Maynard to professor of clinical medicine, Dr. George E. Anderson to clinical professor of medicine, Dr. Walter A. Coakley to clinical professor of plastic and maxillofacial surgery, Dr. George H. Paff to associate professor of anatomy, Dr. John M. Pierce to associate professor of pathology, Dr. Dorothy Loomis to assistant professor of pathology, Dr. George Samuelsen to assistant professor of chemistry, Dr. C. T. Chiaramonte to assistant alignment of the control of the contr sistant clinical professor of dermatology and syphilology, Dr. Arthur E. Lamb to assistant clinical professor of medicine, Dr. A. W. Martin Marino to assistant clinical professor of medicine, Dr. A. W. Martin Marino to assistant clinical professor of surgery, Dr. Ainc worth L. Smith to assistant clinical professor of surgery, and Dr. Thomas D. Dublin to professor and executive head to the Department of Preventive Medicine and Community Health.\*

# THERAPEUTIC TEAMWORK

# Vitamin "B" Complex fortified with Vitamin "C"

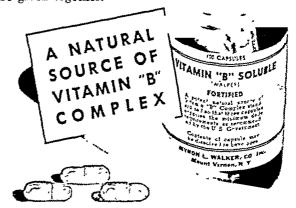

Research has shown that vitamins B and C appear to work as a team in effecting beneficial changes in cellular physiology. This was clinically manifested by improvement in pathology of the upper respiratory mucosa and the retina when the two vitamins were given together.

When only one was used, this favorable reaction did not occur.

Vitamin "B" Soluble (Walker) is derived from brewers yeast—its potency increased so that three capsules meet the minimum daily needs for vitamin B factors recommended by the U. S. Government.

Professional samples sent on request to Myron L. Walker Co. Inc., Mount Vernon, New York.

## VITAMIN "B" SOLUBLE

# ANGINA PECTORIS CARDIORENAL EDEMA

## Note these clinical actions of Theodigital Pulvoids

- Provides effective diuresis
- Stimulates cardiac action
- Reduces edema and dyspnea
- Due to myocardial support and diuresis it releases extravascular pressure, eases cardiac strain

Formula: Phenobarbital  $\frac{1}{2}$  gr., Theobromine  $\frac{1}{2}$  gr., Calcium Salicylate  $\frac{2}{2}$  grs., Powder Digitalis Folium  $\frac{1}{4}$  gr. Bottles of 100.

Write Dept. 2 for samples and literature.

#### [Continued from page 416]

More than two hundred borough doctors crowded the Jewish Hospital's Louria Auditorium on January 10 to watch a demonstration of the wizardry of the Soviet's medical men.

The occasion was a meeting of the Brooklyn Chapter of the American-Soviet Medical Society, at which was shown a new Russian moving picture on nerve transplantation by the Soviet medical scientist, Professor Nikolai N. Burdenko. The film showed the actual operation and transplantation of nerves to restore movement to the limbs of soldiers apparently hopelessly paralyzed by war wounds.

Dr. William Malisoff, professor of biochemistry at Brooklyn Polytechnic Institute, discussed public health in Russia and traced the progress of medical

science there.

Dr. Leo M. Davidoff of the Hospital and Dr. Abraham Stone, national secretary of the society, also spoke.

#### Nassau County

The regular monthly meeting of the county society was held in Mercy Hospital Auditorium in Rockville Centre on the evening of January 25.

The feature of the scientific session was a symposium presented by Justice Henry G. Wenzel, Jr., of the Supreme Court of New York, Jamaica, and Theodore J. Curphey, M.D., Medical Examiner of Nassau County. Justice Wenzel spoke on "The Bench Looks at Medicine," and Dr. Curphey's talk was entitled "Medicine Looks at Law."

#### New York County

The address of the retiring president, Dr. J. Stanley Kenney, and the address of the incoming president, Dr. Conrad Berens, opened the program of the monthly meeting of the county society held on January 25 at 8:15 P.M. at the New York Academy of Medicine. The guest speaker was Maj. Gen. David N. W. Grant, U.S. Army Air Surgeon, of Washington, who gave a talk on "Medical Services of the Army Air Forces."

A film on the Battle of Britain was shown, by courtesy of the U.S. Naval Training Aids Library.

President Berens listed fourteen items to which the

county society plans to devote its energies:

1. Establishing a unified system of medical care for the low- and moderate-income classes of this City, including diagnostic and preventive as well as therapeutic services.

2. Participation in the development of plans for the equitable distribution of physicians throughout

the country.

Thorough study of the educational require-

ments for medical licensure.

4. Continued study and implementing of voluntary plans for improving the quality and distribution of medical care and adjusting its costs to the needs of the time.

5. Continued study of the relationship of the medical profession to the Federal government and

the state agencies.

6. Education and ethical control of nonmedical personnel associated with all branches of medicine.

7. The education, hospital training, practice, and certification of Negro physicians.

The development of adequate hospital facili-

ties where needed.

9. Study of conditions which interfere with the practice of medicine to the detriment of public health.

10. Study of methods of improving and furthering medical education and the exchange of medical ideas and methods, both in the United States and in other countries.

Leadership and closer cooperation with government, industry, commerce, labor, and social agencies for the expansion and improvement of in-

dustrial medical service.

12. Establishment of a concrete plan for the postwar professional rehabilitation of New York

County physicians returning from service.

13. Thorough housecleaning in the field of workmen's compensation and elsewhere to eliminate undesirable professional practices and investigation of the conditions that have produced these practices with a view to preventing their recurrence.

14. Establishment of adequate public relations with a view to better public understanding of the aims and accomplishments of American medicine

and of our society.

Dr. Robert A. Cooke was presented with a gold medal for outstanding contributions to clinical allergy at the sixth annual forum on allergy, held at St. Louis, Missouri, January 22-23. Dr. Cooke delivered the fourth annual forum lecture, on "Observations on Allergic Reaction."

The New York Physicians Association has announced its newly elected officers for 1944 as follows: Elihu Katz, president; Joseph Morse, president-elect; Jacob Buckstein, first vice-president; Rubin Gerber, second vice-president. Samuel Hochman will officiate as recording secretary; Arthur J. Greenberger, as secretary; and Joseph Jonas, as treasurer.

The Society of the Alumni of the College of Physicians and Surgeons, Columbia University, has elected the following officers for the coming year: trustees, William Crawford White, Martin DeForest Smith, Carl Eggers; president, John H. Keating, vice-president, Bernard S. Oppenheimer; secretary, Charles C. Lieb; treasurer, James A. Corscaden; historian, T. Lloyd Tyson; librarian, Martin De Forset Smith

De Forest Smith.

Drs. John H. Morrissey and E. A. Rovenstine
will represent their respective sections—urology
will represent their respective sections—urology and anesthesiology-in the scientific exhibit of the 1944 session of the American Medical Association, to

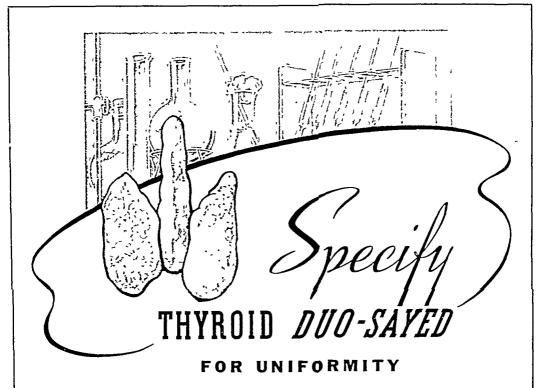

be held in Chicago next June.

The annual Duncan Bulkley lecture of the New York Academy of Medicine was given on January 21 by Dr. George T. Pack on the subject of "Cancer of the Stomach" the Stomach.

The New York Diabetes Association has announced an open meeting to be held on Saturday, February 19, at 8:30 P.M. at the New York Acad-

emy of Medicine. Dr. George E. Anderson, chairman of the committee on internal medicine, will preside over the following program: "Normal Standard in the

Treatment of Young Diabetics," by Dr. Joseph H. Barach, of Pittsburgh, Pennsylvania; "Report on the Philadelphia Diabetes Survey," by Dr. Joseph T. Beardwood, of Philadelphia; and a round-table discussion on diabetes in which the participants will be Drs. Cecil Striker, of Cincinnati, Ohio; Seale Harris, of Birmingham, Alabama; J. West Mitchell, of Pittsburgh, Pennsylvania; Elliott P. Joslin, of Boston; Howard F. Root, of Boston; and Edward S. Dillon, of Philadelphia.

All physicans and medical students are invited to attend this meeting.

#### Ontario County

The first quarterly meeting for 1944 of the county society was held on January 11, at the Canandaigua

Hotel, Canandaigua.

The program for the meeting consisted of a business session at 5:00 p.m., dinner at 6:30 p.m., and a scientific session at 7:30 p.m. Features of the scientific session were a paper entitled, "Report of a Case of Hemolytic Streptococcus Pneumonia Treated with Penicillin," by Dr. P. V. Newland, of the Clifton Springs Sanitarium and Clinic; and a paper on "The Physician's Role in the Home and Farm Accident Control Program," by Dr. J. G. Fred Hiss, of Syracuse.

The next meeting of the society is scheduled for

April 11.

#### Rensselaer County

Dr. Thomas M. Aldrich has resumed practice in Rensselaer after receiving a medical discharge from the Army Medical Corps, in which he served the last year and a half.\*

#### Schenectady County

The regular monthly meeting of the county so-

ciety was held in the Ellis Hospital Library in

Schenectady on February 1.

The subject of the scientific session was "Intrathoracic Tumors and Lymphatic Disease in the Young," and the speaker was Dr. Lloyd Craver, attending physician at Memorial Hospital in New York City and assistant professor of clinical medicine at Cornell University Medical School.

#### Seneca County

Dr. R. Plato Schwartz, associate professor of orthopaedic surgery at the University of Rochester, was a guest speaker before the Seneca School Parent-Teacher Association on January 7.

"Infantile Paralysis: Its Present Status" was discussed by Dr. Schwartz, with the assistance of two research associates, Dr. Harry D. Bouman and Arthur Heath. Dr. Bouman told of some of his

experiments and Mr. Heath showed movies of in-

fantile paralysis treatment.

Dr. Schwartz is a member of the American Medical Association, the American Academy of Orthopaedic Surgery, the American Orthopaedic Society, the Rochester Academy of Medicine, and the Mon-roe County Medical Society, as well as the author and coauthor of a number of articles and books on orthopaedics.

Teachers and mothers of kindergarten pupils

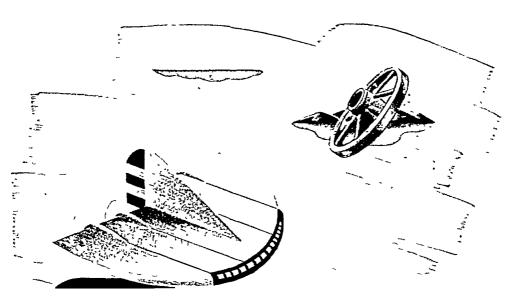

were hostesses.\*

#### Wyoming County

For the fifty-eighth consecutive year members of the Wyoming County Medical Association met on January 13 as guests of Dr. Mary Greene in Castile Sanitarium for luncheon and discussion of medical topics.\*

Note: A list of county society officers for 1944 appears on page 422.

## Medical Legislation

Bulletin No. 2 Issued by the Legislative Bureau of the Medical Society of the State of New York, January 20, 1944

THE annual conference of county society legislative chairmen will be held at the Ten Eyck Hotel in Albany on Thursday, February 24.

The Senate has announced its committees and the personnel of those with which we have dealings is

listed in this bulletin.

The American Medical Association has issued a recent bulletin, No. 29, from which we make the

following excerpts:

'Selective Training and Service Act Amendment: S. 763 has been passed in the Senate and House and has been approved by the President as Public Law No. 197, an act amending the Selective Training

and Service Act of 1940.

"Comment. This law, among other things, directs the President to appoint a commission of five qualified physicians, one an Army officer, one a Navy officer, and three civilian physicians not employed by the Federal Government, to examine the physical, mental, and moral qualifica-tion requirements for admission to the Army, Navy, and Marine Corps and to recommend to the President any changes therein which the commission believes can be made without impairing the efficiency of the armed services. The Director of Selective Service will be required to re-examine rejectees, including those previously discharged from the armed services because of physical disability, to determine if they may qualify under any new standards that may be established. The new law provides, too, that no individuals shall be called for induction, ordered to report to induction stations, or be inducted because of their occupations, or by occupational groups, or by groups in any plant or institutions, except pursuant to a requisition by the land or naval forces for persons in needed medical professional and specialist categories.

"Permanent Medical Service in Veterans' Administration: H. R. 3623, introduced by Representative Rogers, Massachusetts, a bill to insure adequate care of disabled veterans by establishment of a permanent medical service in the Veterans' Administration. Pending in the House Committee on World

War Veterans' Legislation. "Comment. Under th "Comment. Under the provisions of this bill, the Administrator of Veterans' Affairs will be directed to establish in the Veterans' Administration a permanent medical corps to be known as the Veterans' Administration Medical Corps, which will constitute a component part of the military forces of the United States. This bill, apparently, was introduced as a substitute for a previous bill introduced by Representative Rogers, H. R. 2820, which was analyzed in FLB-28, under date of July 15, on page 8.

"Additional Hospital Facilities for Veterans: Under date of September 18, the President submitted to Congress a supplemental estimate of appropriation for the Veterans' Administration, for the fiscal year 1944, in the amount of \$10,356,000. This additional appropriation was for the purpose of providing 3,950 beds for neuropsychiatric patients at thirteen existing facilities of the Veterans' Administration. The House Committee on Appropriations included the requested amount in the First Supplemental National Defense Appropriation Act, 1944 (H. R. 3598). This bill has now become a law. The House Committee in approving the requested

appropriation stated:
"The estimate of \$10,356,000 for construction of additional bed capacity for neuropsychiatric patients is approved without change. The program contemplates the addition of 3,950 beds through enlargement of present facilities at twelve existing veterans' hospitals listed on page 64 of the hearings. While these facilities will not be ready for occupancy for about a year, the incoming load of patients from World War II indicates that they should now be started. As a temporary measure to care for patients of this type, an additional 3,844 beds in existing facilities are being provided through the contraction of small particular and small provided through the contraction of small particular and small particular traction of space.

"Patients admitted to veterans' hospitals as veterans of World War II already total 7,149 and the number is increasing rapidly, a total of 1,476 coming from the armed forces in the month of July. A classification of the total of 7,149 by months commencing in March, 1942 and divided between neumencing in March, 1942, and divided between neuropsychiatric, tubercular, and general cases, is listed on page 69 of the hearing. These data are cumulative to the ord of last Assemble and show that 1550. tive to the end of last August and show that 1,550, or 22 per cent, are tubercular cases; 1,945, or 27 per cent, are general cases; and 3,650, or 51 per cent,

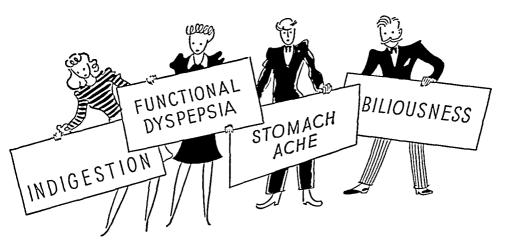

are neuropsychiatric cases.
"It is evident that additional construction will be required from time to time for hospitalization of World War II veterans. The expanding load of veterans of both wars is being given continuous study by the Federal Board for Hospitalization with a view to future construction, having in mind the many beds in service hospitals which may be surplus to the needs of those agencies at the conclusion of the war and bearing in mind the fact that certain of those recently constructed facilities are being designed for postwar use by the Veterans' Administration.' (H. Rept. No. 822, 78th Congress)

"Social Security for Employees of Religious, Charitable, Educational, and Certain Other Organizations: H. R. 3204, introduced by Representative Lynch, New York, a bill to establish and provide for a system of old-age and survivors' insurance for employees of religious, charitable, educational, and certain other organizations. Pending in the House Com-

other organizations. rending in the House conmittee on Ways and Means.

"Comment. This bill proposes to add a new title to the Social Security Act, Title II-A, to be designated 'Federal Old-Age and Survivors' Indesignated 'Federal Old-Age and 'Federal surance for Employees of Religious, Charitable, Educational, and Certain Other Organizations.
Title II of the present act is the section under which federal old-age and survivors' insurance where the company of the company to the comp benefits are made available to present beneficiaries. Benefits to which the employees of organizations now exempt will be entitled under the proposed new Title II-A will be identical with the benefits to which other employees are now entitled under the existing Title II. While the existing provisions of the Social Security Act imposes

[Continued on page 426]

# "Don't rely too much on labels, For too often they are fables"

-Spurgeon, C. H.

Vague symptoms, particularly in the early stages of diseases of the extrahepatic biliary tract, frequently mask the true condition, and delay much needed therapy.

Free drainage through the biliary channels is the primary objective in such conditions. This may be accomplished most efficiently with Cholan DH (pure dehydrocholic acid—Maltbie), not alone through evacuation of the gall-bladder contents—but particularly by a

marked increase (up to 200%) in the flow of bile of especially low viscosity. The use of Cholan DH may frequently forestall the necessity for surgical intervention, by discouraging gall stone formation and the entrenchment of infection.

Contraindications: Occlusive obstruction of biliary tract. Use with caution in acute yellow atrophy, acute hepatitis, eclampsia and progressive jaundice.

Supplied: in bottles of 100, 500 and 1,000 tablets of 33/4 gr. each; also in ampul form, as Cholan DH Sodium (Solution Sodium Dehydrocholate, in 20% concentration), in either 3 cc. or 10 cc. ampuls, 6 to a box.

THE MALTBIE CHEMICAL COMPANY • NEWARK, N. J.

[Continued from page 424]

taxes on employers and employees, the proposed Title II-A contemplates that payments to be made by the exempt organizations and by their employees to the trust fund to be created will be premiums, not taxes.

"Additional Funds for Nurse Training Program: The President, under date of September 29, transmitted to Congress a supplemental estimate of appropriation for the Federal Security Agency for the fiscal year 1944, amounting to \$10,000,000 to be available for carrying on the nurses' training program, authorized by the Bolton Act, for the period January 1 to March 31, 1944. The House Committee on Appropriations gave its approval to \$7,500,000 of the estimate and included that amount in H. R. 3598, the First Supplemental National Defense Appropriation Act, 1944, which has now become a law. In its report on H. R. 3598, the

committee said in part:

"'Approval is given to \$7,500,000 of a budget estimate of \$10,000,000 for training of nurses under the act of June 15, 1943 (Bolton Act). The initial appropriation for this purpose for the fiscal year 1944 was made in the sum of \$45,000,000 in the act of July 12, 1943, toward an entirely new Federal program designed to provide an adequate supply of nurses for the war period. The law provides Federal grants for nurses' training to cover tuition, maintenance, uniforms, and a small stipend to the nurse during the period of the course. At the time the \$45,000,000 was allowed, Congress was advised that the cost for the entire fiscal year would approximate \$65,000,000, and this latter figure has been restated to the committee in the accompanying hearings as still being the estimated total for the year. There have been variables in the program as originally estimated. The number of nurses has not yet reached the number originally estimated and the estimated per capita cost of the 36-month course for student nurses has been revised from the original \$1,250 to \$1,685 per nurse.
"'As of the date of the hearings (October 12)

there were 1,255 nursing schools eligible to give this training and of these 1,003 had applied for approval to give it and 869 had been approved to give it. On the basis of the allotments made from the \$45,000,-000, as of the date of the hearing, approximately 84,000 cadet nurses would receive training, of which 41,000 are new cadet nurses, while the goal for the

year is 65,000 new student nurses for the year.
"The program of \$65,000,000 for the fiscal year depends upon the number of students to enroll for the training. This program, if it materializes, would require \$20,000,000 additional for this fiscal year instead of the \$7,500,000 allowed in the bill. committee feels that at the present rate of recruitment it does not appear likely that the anticipated

enrollment will be attained. It will be necessary to review the program again early in the coming session, and if additional funds are needed they must be provided.' (H. Rept. No. 822, 78th Congress)"

## Bulletin No. 3 Issued by the Legislative Bureau of the Medical Society of the State of New York, January 26, 1944

REMEMBER the date for the annual conference of county society legislative chairmen is February 24 at the Ten Eyck Hotel, Albany.

We reported no new bills in Bulletin No. 2; our space was limited. This list brings you up-to-date.

We mentioned before the bulletins that the Council on Medical Service and Public Relations will issue. These will be sent directly to you from the American Medical Association in Chicago or

through our New York office. Each county so-

ciety legislative committee should consider itself a subcommittee of the Council and comments that you may have regarding the material in the bulletins should be sent to us at the Albany office and we shall see that it is promptly forwarded to the Council headquarters in Chicago.

#### New Bills Introduced

Senate Int. 191-Wallace; Assembly Int. 337-[Continued on page 428]

# EFFECTIVE Ambulant THERAPY

Kamadrox fulfills the three demands of the patient in pepticulcer, gastritis, and gastric hyperacidity: It stops the characteristic pain promptly-keeps the patient ambulatory - permits lesions to proceed to healing. • Kamadrox -composed of magnesium trisilicate (50%), aluminum hydroxide (25%), and colloidal kaolin (25%) -provides promptly effective, profound, and prolonged acid neutralizing power; systematically inert, it cannot lead to alkalosis or acid rebound; it is astringent, demulcent, adsorbent, protective; it exerts no influence on intestinal motility, proves neither laxant nor constipating. Its pleasant taste promptly gains patient cooperation.

# KAMADROX

Kamadrox powder, permitting adjustment in dosage, is supplied in 4-oz. and 1-lb. cans. Kamadrox tablets in bottles of 100 and multiples. Each tablet contains:

Magnesium trisilicate \_\_\_\_\_\_4 grains
Aluminum hydroxide \_\_\_\_\_2 grains
Colloidal kaolin \_\_\_\_\_2 grains

Dose, 1 or 2 tsp. of the powder, well dispersed in water, t.i.d., p.c. Of the tablets, 2 with water, t.i.d. or q.i.d.

## THE S. E. MASSENGILL COMPANY Bristol, Tenn.-Va.

NEW YORK . SAN FRANCISCO . KANSAS CITY

#### [Continued from page 426]

Breed, defines as an occupational disease, for workmen's compensation purposes, deafness caused by occupation subjecting employees to noises, jarring, shaking, or concussion. Referred to the Labor Committees.

Senate Int. 252—Wicks; Assembly Int. 385— Stephens, authorizes the Education Department to lease to any state teachers' college alumni association a portion of the grounds for dormitories; increases the salary of college presidents; provides for a college physician and nurse, fixing salaries and increments; permits the education commissioner to transfer faculty members and employees from one state college to another, and continues extension industrial teacher training courses. Referred to the Education Committee in the Senate and the Ways and Means Committee in the Assembly.

Comment: This is sent you for information. It provides that teachers' colleges may employ physicians and nurses on full time whose duties will be to render medical service to the students and, we presume, the faculty while in the buildings, and also to teach health and hygiene. salary of the physicians will be a minimum of \$4,000, maximum \$5,000; and of the nurses, minimum \$2,400, maximum \$3,000.

Senate Int. 328—Young, provides that the sale of eyeglasses, spectacles, and lenses shall be made only on prescription of a licensed physician or optometrist, instead of having a physician or optometrist in charge of the counter or booth; excepts sale of ready-made reading spectacles or reading glasses equipped with spherical convex lenses, as merchandise in a store, by persons who do not adapt them to the eye and where selection is solely in the discretion of purchaser. Referred to the Education Committee.

Comment: Senator Young introduced this bill last year at the close of the session, too late for

consideration by the Legislature.

Senate Int. 371—Burney, continues to July 1, 1945, provision permitting persons inducted into military service and licensed to practice medicine, dentistry, and other professions and occupations to apply for renewal of license without examination within three months after termination of military service. Referred to the Defense Committee.

Comment: Senator Burney had a similar bill enacted last year which will expire on July 1, The intention now is to continue the law 1944.

for another year.

Senate Int. 380-Anderson; Assembly Int. 504-Knauf, makes it a misdemeanor to include in any newspaper, radio, display, sign, or other advertisement, any statement which misrepresents material, frames or mounting, or price of lenses or of complete eyeglasses, or to advertise frames unless price of frame is advertised with words "without lenses," or to misrepresent service or credit terms. Referred to the Codes Committees.

Comment: Senator Anderson carried this bill last year and it was advanced to third reading. In the Assembly it was sponsored by Mr. Knauf, where it was killed in committee.

Senate Int. 381-Wicks, suspends until July 1, 1945, provisions prohibiting purchase of butterine or oleomargarine by state institutions. Referred to the Agriculture Committee.

Comment: While it is legal to sell and use oleomargarine in the private home, it is not permitted in state institutions. Senator Wicks suggests that for the period of one year the institutions be permitted to use oleomargarine or other butter substitutes.

Senate Int. 409—Joseph; Assembly Int. 197— Jack, establishes in the Health Department a health insurance fund with an administration board of thirteen members appointed by the Governor; fund to be maintained by contributions of employees, employers, and state, and for payment of cash benefits and for maternity and other medical care; allows persons of low income to insure in system, and appropriates \$100,000. Referred to the Finance Committee in the Senate and the Ways and Means Committee in the Assembly.

Comment: Senator Joseph carried this bill last year and in the Assembly it was sponsored by Mr. Jack who has introduced it again this year.

Assembly Int. 176-Austin, extends provisions for the removal of physicians from lists of those authorized to render medical care in workmen's compensation cases to include misconduct in receiving money or other gratuities from purveyor of medical services, including laboratories, drugs optical supplies, and ambulance service. Referred to the Labor Committee.

Assembly Int. 186—Crews, provides person holding a city position in competitive class as physician, medical inspector, dentist, supervising or clinic medical inspector, dentist, supervising or clinic medical inspector. physician after appointment or promotion following examination and who was employed on June 30, 1940, and paid on per annum basis, shall continue in such position on a per annum basis, salary increments and privileges and retirement rights not to be less than those enjoyed on that date. Referred to the Ways and Means Committee.

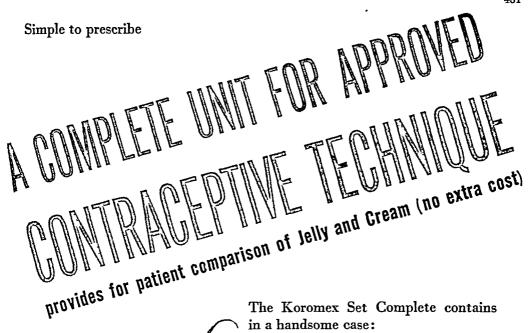

Assembly Int. 252-Farbstein, requires city education boards and school districts maintaining public schools to provide adequate health service for pupils 15 years old and over and facilities to afford physical examination, including x-raying of chest State War Council may help districts financially unable to provide services. Referred to the Education Committee.

Comment: Mr. Farbstein sponsored this bill last year and it was killed in committee.

Assembly Int. 362—Hollowell, provides lists of registered physicians and dentists shall be published and mailed on March 1 in each even-numbered year after 1944, or within ten days, and strikes out provision that additional names of physicians shall be reported. physicians shall be reported quarterly on request to the secretary of the State Medical Society. Referred to the Education Committee.

Comment: Mr. Hollowell proposes that the Department of Education be permitted to publish lish its register of physicians biennially instead of annually. We have called his attention to the fact that the physicians contribute \$2.00 annually for the purpose of having this register made and published, and suggested that if the register is to come out only every two years, should not the assessment be biennial also. He is giving the bill further consideration. He informs us that he introduced it at the request of some physicians in his county. The Department of Education, with the consent of the other pro-fessions, had their laws amended last year to permit of the publication of the register on a biennial basis, but no change was made with regard to the annual assessment. The \$2.00

[Continued on page 430]

in a handsome case:

H-R Diaphragm with special pouch

Koromex Trip Release (takes all size diaphragms)

Tube Koromex Jelly (higher lubricating factor)

Tube Emulsion Cream (lower lubricating factor)

Set Dickinson-Freret Fitting Charts

Price of Koromex Set Complete is only that of the Koromex Diaphragm and Koromex Trip Release Introducer. Attractively packaged with removable label. To prescribe, just write "Koromex Set Complete" and state size of diaphragm.

# Holland-Rantos ompany, Inc.

551 Fifth Avenue, New York 17, N. Y.

[Continued from page 428]

assessment was intended to cover not only the publication of the register but also to help finance the enforcement of the law.

Assembly Int. 369-Molinair, makes it a felony for a person knowing himself to be infected with venereal disease to have intercourse with any person, instead of persons in military or naval service. Referred to the Health Committee.

Assembly Int. 446-Friedman, requires the head of any hospital or asylum to permit performance of ritual circumcision upon a male child born thereat, in accordance with Orthodox Hebrew religious requirements, by rabbi-mohel of the father's own selection, and to provide for observance of religious ceremonies in connection therewith. Referred to the Judiciary Committee.

Assembly Int. 461-Stuart, repeals provision for state aid to tuberculosis patients. Referred to the Ways and Means Committee.

Comment: This bill was introduced at the request of the Department of Health. In 1920 an appropriation of \$10,000 was set aside for the Department of Health to use for investigating private tuberculosis sanitaria. Very few requests were made of the Department in these years and, therefore, it is considered that there is no longer need for the law.

Assembly Int. 505-Knauf, creates in the State Education Department a board for licensing and regulating practice of optical dispensing. Referred to the Ways and Means Committee.

Comment: Same as Senate Int. 9-Wicks, reported in Bulletin No. 1 (February 1 issue,

page 304),

Assembly Int. 518-Backus, provides for care and maintenance at state expense of patients in state tuberculosis hospitals who have no legal settlement in any town or city as defined in Social Welfare Law. Referred to the Health Commit-

Comment: Requires that the county in which a tuberculosis patient has a legal settlement shall be responsible for the hospital care of the patient, provided the hospital care has been authorized by the commissioner of public welfare of the county in which the patient has a legal settlement; and it further requires that the superintendent of the hospital, upon request of the board of supervisors, shall submit a written statement of his inquiry as to the financial circumstances of the patient and his relatives and the reason for his decision that the patient or his relatives are unable to pay either in whole or in part for the care and treatment. In the event that a patient has no legal settlement in any town or city in the state, such care and treatment as he may receive shall be paid by the state.

Assembly Int. 552-J. D. Bennett, authorizes towns to enact ordinances requiring land owners to remove fire and health hazards and weeds and on default permits the town to perform such acts and assess the cost to the owner, notice to be given to nonresident owners. Referred to the Internal Affairs Committee.

#### SESSIONS ON MENTAL-HEALTH CARE OF CHILDREN

The Association for the Advancement of Psychotherapy in cooperation with the Ann Reno Institute of New York City announces the following forum discussions on "Present Needs for Advancement in the Mental-Health Care of Children," arranged by Dr. Ernest Harms, editor of the

journal The Nervous Child:
Tuesday, February 29—"How Institutions Assist in the Mental-Health Care of Children," by Lewis R. Wolberg, M.D., director of the children's ward, Kings Park State Hospital, Kings Park, New York. Tuesday, March 14—"Child Labor Problems—

and Mental-Health Care of Children," by Dr. Gertrude Folks Zimland, general secretary of the

National Child Labor Committee.

Tuesday, March 28—"Leisure-Time Activities and Mental-Health Care of Children," by Dr. E. 44 at 8:15 P.M.

De Alton Partridge, New Jersey Teacher's College,

De Alton Partridge, New Jersey Teacher's Conege, Montclair, New Jersey.

Tuesday, April 11—"Vocational Education—and Mental-Health Care of Children," by Dr. Franklin Keller, principal of the Metropolitan Vocational High School of New York City.

Tuesday, April 25—"Public Welfare—and Mental-Health Care of Children," by Dr. Leone Baumgartner, Department of Health, New York City.

Tuesday, May 9—"The General Practitioner—and Mental-Health Care of Children," by Benjamin Spock, M.D., New York.

The first two sessions were held on January 25 and

The first two sessions were held on January 25 and

February 8. The forum discussions will be held at the Ann Reno Institute, 32 West 86th Street, Manhattan,

#### CHARLES MAYER FELLOWSHIPS AWARDED

The Committee on Medical Education of the New York Academy of Medicine has awarded three of the four Fellowships provided by Dr. Charles Mayer to Dr. Harry Goldblatt of Western Reserve University, the Cancer Research Laboratory of the Mount Sinai Hospital, New York City, and Dr. John R. Murlin of the University of Rochester, New York.

A fourth Fellowship of \$2,000 for research on the "Study of the Relationship Between Precancerous Lesions of the Mouth, Hepatic Insufficiency, and Gastrointestinal Disorders" will be held open for further applications until April 15, 1944.

Applications should be sent to Dr. Mahlon Ash-

Applications should be sent to Dr. Mahlon Ashford, Secretary of the Committee, not later than April 1, 1944.

No Longer is it so much a question of whether to prescribe Aluminum Hydroxide Gel as it is which preparation to select. Its clinical value now well established as an adjunct in the treatment of gastric and duodenal ulcers, convenience of administration ("pourability") and palatability become criteria in selecting the brand for your practice.

Aluminum Hydroxide Gel Squibb, while complying with U. S. P. XII specifications, has also a sufficient fluidity to facilitate easy pouring and it is pleasantly flavored to combat the taste-tedium of prolonged medication. Compared with whatever standards you select, you will find it worth prescribing regularly.

The dose is 4 to 8 cc. orally; or, diluted, it may be used as a continuous intragastric drip. Supplied in 12-ounce bottles.

## Woman's Auxiliary

## To the Medical Society of the State of New York

THE midwinter meeting of the Executive Board of the Woman's Auxiliary of the State of New York was held January 12 and 13, at the De Witt Clinton Hotel, Albany. At the dinner Wednesday

night, twenty-seven members were present.

Mrs. F. Leslie Sullivan, the president, called the meeting to order Thursday morning. About thirty Board members were present. Mrs. C. R. Seymour led the group in prayer and read the Nine-teenth Psalm. Mrs. J. S. Lyons, Albany auxiliary president, welcomed the State president, the mem-bers of the Executive Board, and the auxiliary members. Mrs. W. J. Lavelle responded to Mrs. Lyons' welcome. The business was suspended to listen to Miss Yolande Lyon, field representative of the Public Relations Department of the New York State Medical Society. A discussion followed Miss Lyon's talk.

A letter was received from Mrs. Eben J. Carey National Auxiliary president, saying that she would attend the National Board meeting at Chicago,

November 19.

Mrs. Sullivan, State President, gave her report.

Twenty-eight counties were represented at the National Board meeting. All of the state presidents were against the Wagner-Murray-Dingell

Mrs. Sullivan has visited four counties since

October 1.

Mrs. L. H. Kice and Mrs. A. L. Madden gave valuable suggestions along legislative lines. W. J. Lavelle spoke to the Executive Board. Twentyseven counties have been contacted about legislation. Lewis County may be organized soon. Mrs. G. Scott Towne reported twenty-eight National Bulletin subscriptions since June. Mrs. E. A. Griffin reported that money and cards had been sent to the Physicians' Home. A letter had been received from Dr. Fox thanking the Auxiliary for the There is a vacancy on the Board of the Physicians' Home. A request was received to have someone from the Auxiliary group appointed. The presidents from the following counties were present at the Board meeting: Albany, Broome, Columbia, Herkimer, Montgomery, Orange, Rensselaer, and Schenectady.

#### County News

Albany. The annual conference of the county legislative chairmen will be held at the Ten Eyck Hotel, Albany, February 24. Mrs. Joseph O'C. Kiernan was chairman for a dinner which was served at the USO Variety Club Canteen on January 9.

A tea at the home of Mrs. Elton Dickson in Binghamton marked the January meeting of the auxiliary. The function was in honor of the new members of the auxiliary and also the wives of the interns at the local hospital.

Columbia. The January meeting was held at the Red Cross Headquarters. Mrs. Hugh Henry conducted the business meeting. After the business meeting the members helped with the Red Cross work. Mrs. H. G. Henry received the following letter in answer to the one sent to Congressman

Jay Le Fevre:
"Dear Mrs. Henry: Your letter received expressing your opposition to the passage of the Wagner-Murray-Dingell bills, S. 1161 and H.R. 2861. These bills are now in committee and they must take action before any consideration may be held in the House. I am opposed to the principle of federal control, and am following the progress of the bills in the committees closely. I appreciate your writing me regarding this legislation and would be pleased to receive your comments and suggestions at any time on matters before Congress in which you are interested.

Very sincerely yours, Jay Le Fevre"

The Tuberculosis Eradication Association of Columbia County subscribes to the magazine Hygeia, and sends the magazine to the library of the Hendrick Hudson Chapter of the D.A.R.

Mrs. Henry attended the Board meeting on January 13 at the De Witt Clinton Hotel, Albany.

Fulton. The Christmas party and meeting was held at the home of Mrs. M. F. Drury. Christmas decorations were used throughout the home. Mrs. J. Frederick Sarno presided at the meeting.

members had taken action on the Wagner-Murray. Dingell bill, letters had been written, and the bill After the business session was also discussed. carols were sung under the direction of Mrs. Claude Bledsoe. The January meeting was held at the D.A.R. Chapter House. Refreshments were served by Mrs. Austin Hogan, Mrs. J. F. Sarno, Mrs. William Raymond, and Mrs. William Hesek. The next meeting will be at the home of Mrs. Kenneth Foster in Gloversville.

Montgomery. The auxiliary has invited the public to attend meetings March 7-8 at the Junior High School in Amsterdam, at which time Dr. Joseph Lawrence will speak on the proposed legisla-

Nassau. What a nice idea to have a Christmas party and to bring gifts for foster children.

Rensselaer. The auxiliary met at the home of Mrs. Joseph P Lasko, the president. Mrs. Rachael Newlin, superintendent of the Day Home, was the guest speaker. The topic was "The Effects of War on Children." She stressed the importance of proper nutrition and guidance for children and also dis-cussed the problem of working mothers of young children. Tea was served at the conclusion of the meeting. Mrs. Eugene F. Connally presided at the tea table.

The November meeting was a business meeting preceded by a luncheon at the Queensbury. Mrs. F. Leslie Sullivan, President of New York State Auxiliary, was the guest speaker. Fourteen members attended the meeting. Mrs. Burke Diefendorf, county president, conducted the business meeting.

Notice, Auxiliary members—Subscribe to the National Bulletin. Get in touch with Mrs. G. Scott Towne, 150 Phila Street, Saratoga Springs, New York.

The New York State Annual Convention will be held at the Hotel Pennsylvania, New York City, May 8-12.

## Tuberculosis Abstracts

## Cancer of the Lung-A Growing Problem

There is a masquerading lung disease which often gives quarter for a short time before the fatal issue and whose actions, in many ways, may simulate

those of tuberculosis.

Both diseases are unique, for they masquerade as other acute or chronic conditions of the lung. In neither are symptoms reliable in the early stages. Both diseases are marked by a lack of early reliable physical signs. Both are unique since in the early stages a single X-ray film will usually show some abnormality. Again, they ape one another because in spite of obscure clinical factors the diagnosis can be accurately made in a high percentage of cases. Lastly, there is a similarity between tuberculosis and this masquerading disease, cancer of the lung, as successful treatment depends to such a large degree upon early discovery.

However, the two diseases are different as regards the predominant age groups affected. Tuber-culosis concerns principally the age groups between 15 and 40, whereas lung cancer usually affects those between the ages of 40 and 65. The diseases are totally different in respect to the matter of time. In tuberculosis, time plus rest is often a useful ally of the patient in regaining health. In cancer of the lung the element of time is always an enemy of the patient. Prolonged observation and rest treatment never improve the situation, but rob the

patient of his only chance for possible cure.

In 165 cases of lung cancer it was found that they first consulted a doctor because of symptoms usually associated with almost any chronic chest condition. A review of these symptoms suggests it would be impossible to set apart any group of com-plaints that could be regarded as pathognomonic of pulmonary malignancy. Nevertheless, 82 per cent of all the patients reported chronic cough, while no less than 92 per cent had as a first symptom something that called for attention to be directed to the chest when first the physician was consulted. Besides cough, other common symptoms included chest pain, chills and fever, hemoptysis, dyspnea, loss of weight, and weakness.

Reviewing the physical signs elicited it is again impossible to outline a specific and significant grouping any more suggestive of cancer than of other chronic pulmonary conditions. Cases examined in the early stages often presented no physical signs. When present, the signs were of considerable variety and frequently misleading. They inable variety and frequently misleading. cluded evidence of congestion, consolidation, fluid, localized emphysema, cavitation, bronchial obstruction, mediastinal shift, and other phenomena varying with the case, thus emphasizing the unreliability of simple physical signs in the differential

diagnosis of this condition.

Of the 165 cases, 104 (63 per cent) were incorrectly diagnosed by the first doctor consulted. In view of the confused picture of misleading symptoms and physical findings, perhaps this majority in favor of error is not completely surprising, but the sobering thought emerges that treatment based upon an erroneous diagnosis was maintained for long periods of time, aimed at such supposed conditions as tuberculosis, 40 cases; unresolved pneumonia, 18 cases; lung abscess, 13 cases; bronchitis, 11 cases; asthma, 5; heart disease, 4; pleurisy, 4; metastatic tumors, 2; and miscellaneous, 9 cases. Most notable fact

was the high frequency of false diagnoses of tuberculosis.

Unfortunately, lung cancer was not unmasked in far too many cases until long after the patient first visited a physician. It was possible in 125 case histories to determine how speedily a verified diagnosis was reached. Two facts stood out boldly. First, 36 per cent of the patients placed themselves under medical supervision at onset or within one month of the onset of symptoms. Second, the average patient consulted a doctor within three months of onset but did not receive benefit of a chest x-ray for an additional three months. The true diagnosis was not arrived at until nine months had elapsed from the time when the first doctor saw the patient.

The x-ray, without doubt, is by far the most valuable aid in apprehending pulmonary disease, but a distinction is necessary between its ability to yield presumptive and absolute evidence. In 98 per cent of this series of cases the initial film revealed trouble was present. An explanation of the delay in reaching a final diagnosis may be found in the fact that in the majority of instances the primary pathologic process failed to produce upon the film or the fluoroscopic screen a shadow of

itself.

Those abnormalities that did appear were secondary effects due to the presence of the neoplasm and were of such variability as to be susceptible of a wide range of interpretation.

In 95 per cent of the cases it was possible to establish an unequivocal diagnosis during life, bronchoscopy being the leading method of obtaining tissue, and having been employed in 103 cases. In 39 other cases surgical exploration was used. Metastases were sectioned in a few cases, aspiration was the method in another small group, while the remaining 5 per cent were diagnosed only after

postmortem examination.

For a decade surgery has been available in the treatment of lung cancer. A creditable showing has been made during this pioneering period. For example, 2 out of every 5 cases surgically explored have been found to be free of extension of the cancer extrapulmonarily. The percentage of the entire group of verified cases for whom there was some hope of cure was 20 per cent. This seems an encouraging ratio when we recall that prior to 1933 there was no reason to regard the condition as anything but incurable. As a reward for our efforts, 20 patients, or 13 per cent, remain as the net salvage from the entire series of 156 verified cases of primary lung cancer, out of 32 individuals selected for an attempt at curative resection. These 20 patients are all reasonably well and devoid of evidence of metastatic disease, while five of them can be referred to as "cures" in so far as they have now passed the fiveyear mark.

In considering practical steps toward bringing cases of lung cancer to light during their curable stage we can learn valuable lessons from the record on tuberculosis case finding. Physicians have been taught that if tuberculosis is to be discovered during its minimal stage it is necessary not to search for absent or insignificant symptoms and physical signs but to go immediately to the x-ray. The

# The OK ration for war and peace

As further and further studies are made on bread, the clearer it becomes why bread has been a fundamental food throughout the ages.

And why, today more than ever, it deserves that position.

Bread is one of the best sources of foodenergy—needed for the fight in the soldier's diet, the work in the diet of those back home.

It supplies protein. Recent findings show bread is a good source of threo-

nine, one of the eight essential aminoacids of the body-building proteins.

And as white bread is made today, it provides valuable amounts of thiamin, ribo-flavin, niacin and iron.

This is why bread occupies an important place in one of the seven basic food groups which should be eaten every day.

It's why physicians will find that, in these days and in the days to come, bread will continue to be a fundamental food in every normal diet, and a valuable asset in many of the special diets they pre-

# COLLOID: L // IO YIZABLE IRON

## In the CHLOROSIS YEARS

WHILE the incidence of frank chlorosis is today much lower than in former years, there is nevertheless a decided tendency for adolescent growing girls to develop a characteristic clinical triumvirate—anemia, malnutrition and digestive malfunction. In combating this syndrome, colloidal iron-protein has major therapeutic advantages over the iron salts. The salts (sulphates, citrates, etc.) are split up in the stomach with release of ions likely to be astringent and irritating. In the intestine, such ions form inert precipitates which are dehydrating, constipating and difficult to assimilate.

But the iron in OVOFERRIN is colloidal iron protein. It is not in ionic form It is little affected by the gastric juice. It is stable and cannot irri-

tate. It arrives in the intestine as a fully hydrated colloidal oxide which cannot constipate and is readily assimilable. It is noteworthy that most nutriment is absorbed in colloidal form.

Not only is OVOFERRIN a rapid bloodbuilder, free from irritating and constipating effects, but it appears to have a decided propensity for appetite stimulation. Important also in insuring patient co-operation in these finicky young ladies is the fact that it is tasteless and odorless and that it cannot stain or dissolve tooth enamel. But it achieves these effects, not by coating or sweetening or masking, but by the simple inherent fact of its colloidal form. Dosage—one tablespoonful in a little milk or water at meals and bedtime.

[Continued from page 434]

same can be said for the apprehension of early lung

How may the first doctor consulted set in motion this mechanism of early discovery? He may save valuable time for his patient if he remembers:

That cancer of the lung is now one of the most important diseases of the chest in patients within the age period from 40 to 65 years, particularly in males.

2. That many patients do seek help at a time

when the lesion is still confined to the lung.

3. That symptoms and signs are either lacking or misleading in the early stages.

That the earliest lesions will in almost every case produce some telltale shadow on the x-ray film, and

5. Finally, that there are two methods available for clinching the diagnosis:

First, that the majority of lesions are visible bronchoscopically and accessible for biopsy, and second, that when the suspicion cannot be verified in this way, it is possible to explore the chest safely by surgical means, settle the diagnosis, and carry out curative treatment if necessary.—A Common Masquerading Lung Disease, Richard H. Overholt, M.D., Diseases of the Chest, May-June, 1943. Reprinted from Tuberculosis Abstracts, December,

#### UROLOGY AWARD

The American Urological Association offers an annual award "not to exceed \$500" for an essay (or essays) on the result of some specific clinical or laboratory research in urology. The amount of the prize is based on the merits of the work presented, and if the Committee on Scientific Research deems none of the offerings worthy, no award will be made. Competitors shall be limited to residents in urology in recognized hospitals and to urologists who have been in such specific practice for not more than five years. All interested should write the Secretary, for full particulars.

The selected essay (or essays) will appear on the program of the forthcoming meeting of the American Urological Association, June 19-June 22, 1944, Hotel Jefferson, St. Louis, Missouri.

Essays must be in the hands of the Secretary, Dr. Thomas D. Moore, 899 Madison Avenue, Memphis, Tennessee, on or before March 15, 1944.

#### NEW JOURNAL ON ALLERGY

The Annals of Allergy, published by the American

College of Allergists, recently made its appearance. Dr. French K. Hansel, of St. Louis, is editor-in-chief. The editorial board includes a staff of corresponding editors from fifteen foreign countries and the United States possessions and is composed of specialists who have made some personal contributions to the field as related to their own particular specialty, internists, otolaryngologists and ophthalmologists, pediatricians, dermatologists, gastro-enterologists, immunologists, bacteriologists (mycol-ogists), pharmacologists, biochemists, botanists, plant pathologists, and others. The college was incorporated in November, 1942, and its objectives are to supplement the work of existing allergy groups as well as to "emphasize and consider numerous phases of the subject heretofore overlooked." Dr. Frederick W. Wittich, of Minneapolis, is secretary of the college.

## in HYPERTENSION

Answer it with HEPVISC

High blood pressure brought down to safer levels by gradual, prolonged action of HEPVISC. Also relieves headaches and dizziness.

> DOSE: 1-2 tablets t.i.d., after meals. Sample and formula on request.

The potentiation of the central action of phenobarbital by the belladonna lkaloids (Friedberg, Arch. f. exp. P. & P. CLX, 276) renders possible trainment of desired effects with relatively small doses, thus avoiding hang over" and other unpleasant side-actions. In contrast to galenical reparations of belladonna, such as the tincture, Belbarb has always the ame proportion of the alkaloids.

ndications: Neuroses, migraine, functional digestive and circulatory disurbances, vomiting of pregnancy, menopausal disturbances, hypertension, etc.

Formula: Each tablet contains ¼ grain phenobarbital and the three chief alkaloids, equivalent approximately to 9 minims of tincture of belladonna.

Belbarb No. 2 has the same alkaloidal content but 1/2 grain phenobarbital per tablet.

same can be said for the apprehension of early lung cancer.

How may the first doctor consulted set in motion this mechanism of early discovery? He may save valuable time for his patient if he remembers:

1. That cancer of the lung is now one of the most important diseases of the chest in patients within the age period from 40 to 65 years, particularly in males.

2. That many patients do seek help at a time

when the lesion is still confined to the lung.

3. That symptoms and signs are either lacking or misleading in the early stages.

- That the earliest lesions will in almost every case produce some telltale shadow on the x-ray film, and
- 5. Finally, that there are two methods available for clinching the diagnosis:

First, that the majority of lesions are visible bronchoscopically and accessible for biopsy, and second, that when the suspicion cannot be verified in this way, it is possible to explore the chest safely by surgical means, settle the diagnosis, and carry out curative treatment if necessary.—A Common Masquerading Lung Disease, Richard H. Overholl, M.D., Diseases of the Chest, May-June, 1945. Reprinted from Tuberculosis Abstracts, December, 1948.

#### UROLOGY AWARD

The American Urological Association offers an annual award "not to exceed \$500" for an essay (or essays) on the result of some specific clinical or laboratory research in urology. The amount of the prize is based on the merits of the work presented, and if the Committee on Scientific Research deems none of the offerings worthy, no award will be made. Competitors shall be limited to residents in urology in recognized hospitals and to urologists who have been in such specific practice for not more than five years. All interested should write the Secretary, for full particulars.

The selected essay (or essays) will appear on the program of the forthcoming meeting of the American Urological Association, June 19-June 22, 1944,

Hotel Jefferson, St. Louis, Missouri.

Essays must be in the hands of the Secretary, Dr. Thomas D. Moore, 899 Madison Avenue, Memphis, Tennessee, on or before March 15, 1944.

#### NEW JOURNAL ON ALLERGY

The Annals of Allergy, published by the American College of Allergists, recently made its appearance. Dr. French K. Hansel, of St. Louis, is editor-in-

Dr. French K. Hansel, of St. Louis, is editor-inchief. The editorial board includes a staff of corresponding editors from fifteen foreign countries and the United States possessions and is composed of specialists who have made some personal contributions to the field as related to their own particular specialty, internists, otolaryngologists and ophthal-mologists, pediatricians, dermatologists, gastroenterologists, immunologists, bacteriologists (mycologists), pharmacologists, biochemists, botanists, plant pathologists, and others. The college was incorporated in November, 1942, and its objectives are to supplement the work of existing allergy groups as well as to "emphasize and consider numerous phases of the subject heretofore overlooked." Dr. Frederick W. Wittich, of Minneapolis, is secretary of the college.

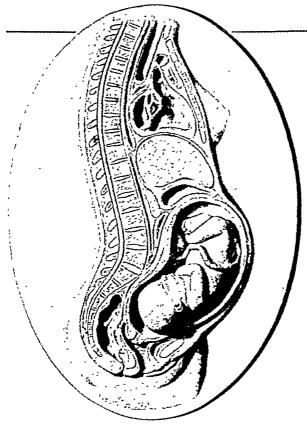

## in HYPERTENSION

Answer it with HEPVISC

High blood pressure brought down to safer levels by gradual, prolonged action of HEPVISC. Also relieves headaches and dizziness.

DOSE: 1-2 tablets t.i.d., after meals. Sample and formula on request.

## ANATOMY OF PREGNANCY

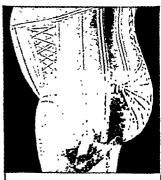

#### Seven Lunar Months

One of a series of life-size sculptured models made for S. H. Camp and Company by Charlotte S. Holt.

Beginning tension on recti muscles. Uterine fundus 5.5 cm. above umbilicus. Cephalic presentation determined. Visceral displacement (upward and lateral). Lumbar and dorsal curves increased. Relaxation of sacroiliac and pubic joints.

THE effectiveness of Camp prenatal supports arises from the fact that the pelvis (the base of the body) can be fitted evenly and accurately and to the desired degree of firmness.

Such a foundation about the pelvis provides for prime assistance in holding the uterus in better position, thus not only conserving the abdominal muscles and fasciae, but also helping in balancing the spine; no constriction of the body at any point; protection of the relaxed pelvic joints is assured; ample support of the lumbar spine afforded.

Camp Prenatal Supports are moderately priced and easily adjusted by the Camp Patented Adjustment feature.

#### SHOES AS THERAPEUTIC AGENTS

No doctor can ignore that shoe therapy is a major factor in the treatment of many foot disorders. In some cases, however, when further medical or surgical treatment is required, the shoes must be adjusted to conform to any changes such treatments make in the shape or size of the feet.

Pediforme shoes are prepared through experienced craftsmen to make the necessary adjustments as prescribed by the orthopedic surgeon or physician in these cases.

With purchases restricted it is readily apparent that substantial shoes, capable of reconstruction or easy adjustment, should be prescribed. For all practical purposes, Pediforme footwear may well be considered in shoe therapy.

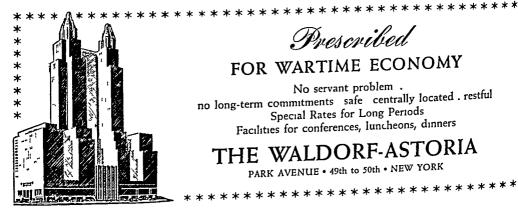

A SHOE FOR EVERY MEMBER OF THE FAMILY... A SHOE FOR EVERY INDIVIDUAL REQUIREMENT.

GOLD PHARMACAL CO.

### MARINOL

(IMPROVED FORMULA)

MARINOL (IMPROVED FORMULA) is an homogenized emulsion of cod liver oil and vegetable oils fortified with fish liver oils of high vitamin A potency to which has been added pure vitamin D<sub>3</sub>.

#### OUTSTANDING PROPERTIES –

PALATABILITY: The desirable properties of the fish liver oils have been retained without the disagreeable taste and odor.

HOMOGENIZATION: This assures a uniform and stable product that permits of easy miscibility with milk, special formulae, fruit or vegetable juices, or with water.

HIGH VITAMIN POTENCY: 5,000 U.S.P. units of vitamin A and 500 U.S.P. units of vitamin D<sub>3</sub> supply the daily

minimum requirements (FDA) in one teaspoonful.

LOW COST: A single teaspoonful daily is a prophylactic dose.

FOOD VALUE: Fish liver and vegetable oils supply another desirable property—that of caloric value.

EASY ADMINISTRATION is possible because of unusual potency of small dose.

CONSUMER PRICE: Bottle of 6 fl. oz. 85 cents. Bottle of 12 fl. oz. \$1.50 (M.P.R. 392). HOW SUPPLIED: Bottles of 6 fl. oz. and 12 fl. oz.

#### LOST-A LADDER

Walter Legge, writing in the Granby Leader-Mail about a recent trip to the Maritime Provinces, told

the following story:

On one of the fast trains of the Canadian National Railways between Montreal and Halifax, a lady was trying to get into an upper berth but the porter could not find the ladder. "Lady," he said, "I have been a porter for eighteen years and this is the first time I ever lost my ladder. I had it right here a minute ago."

At this moment, an English sailor popped his head out of an upper berth and said, "I'll lend you my ladder 'til morning." He had pulled the ladder

into the berth with him.

#### RAIL TICKET SCALPING OUT

An announcement made by the ODT of a nationwide campaign to stamp out a black market in railroad ticket reservations was reported in the January 1st issue of Travel Items. In connection with this effort, the ODT has enlisted the aid of the FBI, the Secret Service, and the Internal Revenue Bureau.

The officials of these organizations appeal to the public to "give us specific cases", citing dates,

persons involved, and train space bought.

Representative Halleck (R., Ind.) of the Interstate Commerce Committee, believes legislative action may be required to check this black market. He advised, however, that a distinction be made between black market gouging and legitimate service charges for handling tickets.

In New York City, Mayor La Guardia has shown one way to combat the black market by signing a local law that makes it a misdemeanor, which can bring a \$100 fine or ten days in jail, for any individual or business concern to charge more than \$1 for providing railroad, plane or bus tickets or accommodations. This, however, does not apply to tickets to or from places outside the continental United States and Canada, except Alaska, or to existing contracts with agencies covering tourist or travel service. The FBI and private detectives are investigating ticket scalping in New York, Chicago, Miami and other centers. Railroad spokesman reported several discharges of employees found to be collaborating with the black market. While railroad investigators have been checking the situation, it is difficult for a railroad to tell just when a ticket is being purchased legitimately and when it may be going to a speculator.

So it is more or less up to the public to

help.

Numerous varieties of black market, or some-thing close to it, have been reported. There has been block buying of reservations by large industrial concerns, some of them turned back to the railroads at the last minute. Some black market operators are believed to have kept "runners" on the lookout for train space wherever it can be bought, including pickup of last minute cancellations.

A new law planned by Congressmen will require a federal license for all persons doing business as travel agents within the United States. Requirements to obtain a license will be good character, financial responsibility, and at least three years experience in the general travel field. A board of examiners will pass on the qualifications of all applicants.

# Important Wartime change in Biolac!

### Borden's complete infant formula

To conserve vital tin, we are now packaging Biolac in 13-fl.-oz. cans instead of the former 16-fl.-oz. size. The new Biolac is more highly concentrated but the new smaller can contains identically the same food values.

Now each fl. oz. of Biolac should be diluted with  $1\frac{1}{2}$  fl. ozs. of water and not 1 fl. oz. as formerly.

Briefly, the situation on Biolac is this ...

When it became necessary to package Biolac in 13-fl.-oz. instead of 16-fl.-oz. tins, we set our chemists to work to concentrate the food elements to fit the container.

Tests of the new concentrate show identical food values in the smaller container. The new container still makes one full quart of standard formula.

Biolac still provides all nutritional

needs of the young infant except vitamin C. The price remains the same.

#### Change in Formula-Making Directions

For standard formulas the new, more concentrated Biolac should be diluted with 1½ parts water (instead of using equal parts of Biolac and water).

For detailed information write to Borden's Prescription Products Division, 350 Madison Avenue, New York 17, N. Y.

# NO LACK IN

Borden's complete infant formula

Biolac is prepared from whole milk, skim milk, lactose, vitamin B<sub>1</sub>, concentrate of vitamins A and D from cod liver oil, and ferric citrate. Evaporated, homogenized, sterilized.

### 5 forms of Vitamins A and D

#### VI-DELTA

#### Lederle

The Pharmaceutical and research experience of Lederle Laboratories have combined to make available five different dosage forms for the administration of vitamins A and D. During the past several years, patients have received these products exceptionally well.

"VI-DELTA EMULSION Lederle"—a pleasant tasting, natural orange-flavored emulsion that is enthusiastically accepted by children.

8 fl. oz. and 1 pint (16 fl. oz )

"VI-DELTA LIQUID CONCENTRATE Lederle"—high potency, convenient dropper-bottle form, particularly useful where economy and rapidity of administration to a number of babies or patients, are desired.

5 CC. AND 30 CC. DROPPER BOTTLES

"VI-DELTA CLIPSULES Lederle"—clean, convenient, sanitary and containing a measured dose. The end of one of the CLIPSULES is removed with scissors and the contents squeezed upon the baby's tongue. No droppers—no waste—no disagreeable fishy odor.

PACKAGE OF 32 CLIPSULES

"VI-DELTA CAPSULES Lederle"—convenient, tasteless method of administering concentrated vitamins A and D to older children and adults.

50, 100 AND 1,000 CAPSULES

"VI-DELTA LENTAES Lederle"—a new type thin, lens-shaped, gelatin-coated tablet containing the fat-soluble vitamins in a highly emulsified solid state. Lentabs are especially easy to swallow and the emulsified content promotes efficient absorption.

100 AND 1,000 LENTABS

OVER 30 Lederle VITAMIN PRODUCTS PROVIDE A FORM FOR EVERY MEDICAL DEMAND · · · ·

Crauling the crags at dawn . . . Exposed on rocky ledges in the blistering noonday sun . . . Fighting pain and death through the freezing night . . .

Unarmed and unafraid, the medical officer on mountain duty is often marooned amid harrowing hardships for days on end, unrelieved except for an occasional cigarette...a cheering Camel most likely...the soldier's favorite smoke.

Camel is first choice of the armed forces\* because Camel rates first for mildness, first for fine flavor. Remember that—when you send cigarettes to friends and relatives in service. Send Camels—the brand that's sure to please.

### Ist in the service

\*With men in the Army, the Navy, the Marine Corps, and the Coast Guard, the favorite cigarette is Camel. (Based on actual sales records.)

as a Valuable Aid Before and After BILIARY TRACT SURGERY

When Decholin (dehydrocholic acid) or its sodium salt (intravenous) is given prior to surgery, the copious outpouring of thin liver-bile, secreted under increased pressure, makes bile ducts and gallbladder stand out prominently at operation, facilitating identification and manipulation.

Postoperatively, when external drainage is not employed Decholin tablets, usually tolerated after 48 or 72 hours, improve common duct drainage, aid in the removal of debris, reduce the discomfort. When drainage is used, Decholin hastens return of bile secretion, aids in disposing of inspissated bile, gravel, small stones overlooked at surgery. Contraindicated only in complete biliary obstruction.

CLINICALLY EFFECTIVE LOW TOXICITY EFFECTIVELY ENTERIC COATED

State Society Officers......456, 458, 462

#### AND DISEASE CORONARY

Medical authorities in journals and books have substantiated the value of Theobromine Sodium Acetate in treating certain Cardiovascular and Renal Diseases. Actual clinical use has proven the usefulness of Thesodate (Brewer).

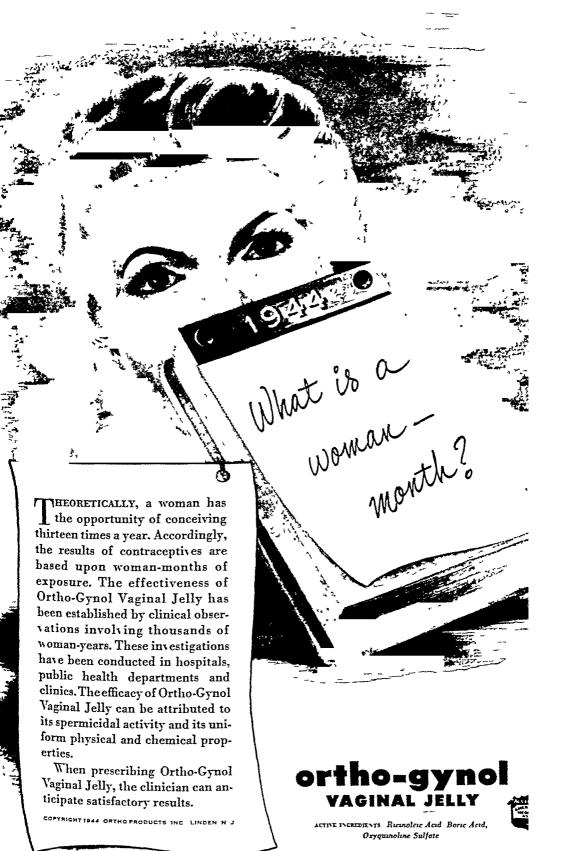

The enteric coating of Thesodate tablets permits adequate dosage, so necessary for best results with xanthines, for as prolonged a period of time as necessary.

Supplied with or without Phenobarbital, also with Potassium lodide and Phenobarbital, in potencies for controllable dosage.

Samples and literature on request.

#### Lupolysin in obesity FEMALE

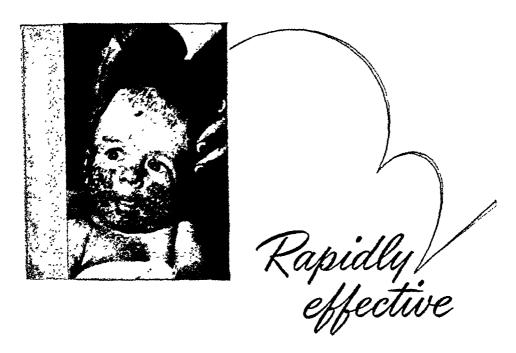

MALE

SAFELY DEPENDABLE

Lipolysin increases fat oxidation through stimulation of metabolic processes ... for safe, gentle and gradual reduction of excess poundage. A dependable pluriglandular preparation of high purity. No dinitrophenol.

Tablets and Capsules: bottles of 100. Ampuls: boxes of 12 and 100. Physicians are invited to send for literature. Address Dept N.

Broadway , New York CAVENDISH PHARMACEUTICAL CORP., 25 West

### AND DOUBLY APPRECIATED BY THE MOTHER

Almost a decade of clinical use, at one of America's outstanding pediatric clinics, has established the remarkable value of Tarbonis\* in infantile eczema.

Pruritus is promptly alleviated, scratching ceases, dermic lymph circulation improves (as demonstrated by rapid decongestion of the involved areas), and healing promptly ensues.

Tarbonis is doubly appreciated by the mother of the infant because it produces its therapeutic benefits without any of the disagreeable features of the usual tar preparations. It is ODORLESS, free from all tarry odor; NON-STAINING and NON-SOILING; it is GREASELESS, since it is a vanishing-type cream. No removal is required before reapplication.

The high therapeutic efficacy of Tarbonis, equally valuable in all other forms of eczema, in psoriasis, in many forms of dermatitis venenata, is attributable to its especially processed Liquor Carbonis Detergens, of which it combines 5% with lanolin and menthol in a special vanishing-type cream. • Tarbonis is available on prescription through all pharmacies in 2½ oz. and 8 oz. jars and through accredited surgical supply houses in 1 lb. and 6 lb. containers.

Physicians are invited to send for clinical test sample and complimentary copy of the new, comprehensive brochure on tar therapy. THE TARBONIS COMPANY, 1220 Huron Road, Cleveland 15, Ohio.

# IN IODIDE ADMINISTRATION

THE OLD-messy, inconvenient liquid formula fell far short of providing accurate dosage of Potassium Iodide. Droppers differed; drops varied with size of dropper tip, the angle at which it was held, and the specific gravity or viscosity of the solution. Compare this guesswork with...

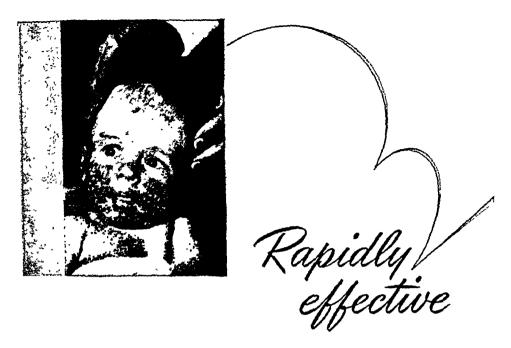

I GRAM POTASSIUM IODIDE, U.S.P. (15.43 grains) Enteric Coated Tablets Supplied in bottles of 100 on prescription only

THE NEW-accurate, controllable and less obnoxious administration of Enkide tablets when Iodide is indicated, assures less distress for patients and less possibility of skipping doses. The enteric coating minimizes gastric distress and eliminates taste. Tablet form makes the dose easier and more convenient to take.

# WHEN VITAMIN DEFICIENCY IS SUSPECTED

# ONE CAPSULE DAILY ASSURES VITAMIN ADEQUACY

Vioctin presents the eight vitamins considered nutritionally essential, in amounts which — with one exception — closely approach the recommended allowances of the National Research Council. Of vitamin C it contributes 30 mg., 600 U.S.P. units. • Whenever vitamin supplementation is indicated, or when vitamin deficiency is suspected, one Vioctin capsule (3 minim size) daily assures protective adequacy. • Vioctin is notable for its low cost to the patient.

THE PAUL PLESSNER COMPANY
35 YEARS OF ETHICAL SERVICE
DETROIT 2 MICHIGAN

Each capsule of Vioctin contains not less than:

Vitamin A.....5000 U.S.P. Units Vitamin D.....800 U.S.P. Units

In Congestive Heart Failure

A well tolerated,

quickly acting diuretic and myocardial stimulant

DOSE: 1 tablet (4 grains) two to four times a day.

BILHUBER-KNOLL CORP.

**ORANGE** NEW JERSEY.

Zymenol is indicated in either the irritable, unstable or stagnant bowel because it is a natural approach to the two basic problems of Gastro-Intestinal Dysfunction;

#### ASSURES HORMAL INTESTINAL CONTENT

... through brewers yeast enzymatic action\*

#### RESTORES NORMAL INTESTINAL MOTILITY

... with complete natural vitamin B complex\*

This twofold natural therapy restores normal bowel function without catharsis, artificial bulkage or large doses of mineral oil. Cannot affect vitamin absorption. Avoids leakage.

Teaspoon Dosage Economical Sugar Free
\*LymenoL contains Pure Aqueous Brewers Yeast (no live cells)

White For FREE Clinical Size

### The "Smoothage" Factor in **CONSTIPATION MANAGEMENT**

TETAMUCIL, providing "smoothage"-a modern concept for treatment of constipation—is accepted by the Council on Pharmacy and Chemistry of the American Medical Association.

Metamucil, a product of Searle Research, presents the refined mucilloid which renders possible the application of "smoothage" therapy in the bowel.

#### METAMUCIL

is the highly purified, non-irritating extract of Plantago ovata (50%) combined with anhydrous dextrose (50%). Metamucil mixes readily with liquids. Metamucil is palatable. Metamucil is easy to take.

Supplied in 1-lb., 8-oz. and 4-oz. containers.

#### G.D. SEARLE & CO.

CHICAGO

New York Kansas City San Francisco

Metamucil is the registered trademark of G. D. Searle & Co.

### ROUTINE URINALYSIS SIMPLIFIED

presenting two important short cuts

#### ı. Galatest

(DRY REAGENT FOR URINE SUGAR)

### 2. Acetone Test

(DENCO)

Acetone Test (Denco) further simplifies Routine Urine Analysis. Detects presence or absence of acetone in urine in one minute. Color reaction is identical to that found in violet ring tests. Trace of acetone turns the powder light lavender—larger amounts to dark purple. Just as easy and direct as Galatest (dry reagent for urine sugar):

#### THE SAME SIMPLE TECHNIQUE FOR BOTH TESTS

I. A little powder.

2. A little urine.

Color reaction instantly.

A carrying case containing one vial of Acetone Test (Denco) and one vial of Galatest is now available for the medical bag or for the diabetic patient. The case contains a medicine dropper and a Galatest color chart.

"Accepted for advertising in the Journal of the American Medical Association"

### HUNLIZE THE ANALOESIC

IN Acute and chronic tonsillitis Pharyngitis "Sore throat" of influenza, grippe Post-tonsillectomy states

Pharyngeal irritation associated with acute coryza and non-specific upper-respiratory infections

### ™*Dillard'a* Aspergum

Brings the analgesic (acetylsalicylic acid) into immediate and *prolonged* contact with inflamed, painful areas—the tonsillar region and pharyngeal mucosa—areas seldom reached, and then only briefly, by gargles or irrigations.

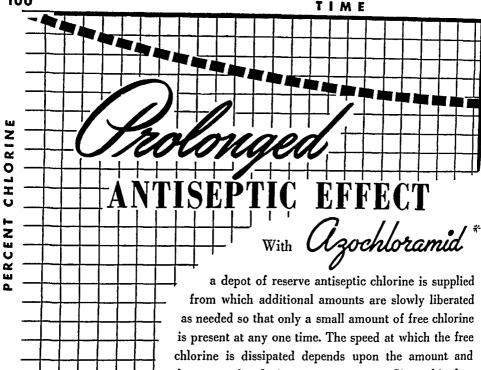

The gentle stimulation of muscular action resulting from chewing Aspergum helps relieve local spasticity and stiffness, helps promote tissue repair. With throat soreness and irritation relieved, the patient is more comfortable, partakes of an adequate diet earlier, enjoys a more rapid convalescence.

Aspergum's value is still further emphasized by the fact that most children and many adults cannot or will not gargle effectively.

Ethically promoted—not advertised to the laity. White Laboratories, Inc., Pharmaceutical Manufacturers, Newark 7, N. J.

WHITE'S

from which additional amounts are slowly liberated as needed so that only a small amount of free chlorine is present at any one time. The speed at which the free chlorine is dissipated depends upon the amount and character of reducing groups present. Since this free chlorine has a great affinity for strongly reducing groups usually present in micro-organisms, the effect of AZOCHLORAMID on tissues is mild.

Thus, controlled hydrolysis of AZOCHLORAMID and slow dissipation of its chlorine content provide a sustained antiseptic actionreducing frequency of dressings (and accompanying trauma) and resulting in conservation of time on the part of medical attendants. Trade Mark Reg. U. S. Pat. Off.

NEUTRALIZING POWER

An Outstanding Pharmaco-Chemical Achievement

Magnesium Trisilicate In a True Magma

Contains No Aluminum Hydroxide

**Not Constipating** 

Clinical response to Magmasil sets a new high standard in the treatment of peptic ulcer, gastritis, hyperchlorhydria. Since it is free from the drawbacks of many other antacid medications, Magmasil therapy is marked by dependable patient cooperation.

Magmasil cannot lead to alkalosis, to chloride depletion, to constipation. In the dosage employed, it exerts no influence whatsoever on intestinal motility.

Since its profound neutralizing power (86 cc. of N/10 HCl per teaspoonful) is exerted over fully four hours after ingestion, fewer doses are needed, and pain and pyrosis do not recur. The customary eleven o'clock dose usually holds the patient comfortable through the night.

Because of its high protective action Magmasil leads to rapid remission and unimpeded healing.

Physicians are invited to send for samples and a complimentary copy of the brochure "Twenty Years of Progress in Ulcer Therapy."

THOS. LEEMING & CO., INC. 155 E. 44th St. New York, N. Y.

Magmasil is available through all pharmacies in 12 oz. bottles.

HEMPSTEAD, L. I., 241 Fulton Ave. HACKENSACK, 299 Main St.

IN DISORDERS OF GASTRIC FUNCTION

GASTRON is an original extract of the organic and inorganic constituents of the entire mucosa of the hog-stomach including the pylorus. The acidified and aromatized extract is incorporated in an aqueous-glycerin-propylene glycol menstruum which preserves the enzymatic activity. The preparation contains no alcohol. It is accurately standardized by assay.

Gastron is indicated as replacement therapy in atrophic gastritis, and as an aid in the treatment of chronic gastritis. It is of value as adjunctive treatment in the anemias, and in certain gastric deficiencies associated with convalescence and old age. It is worthy of trial in the nausea and vomiting of pregnancy.

GASTRON WITH IRON is available also for prescription use

# Clinical Response

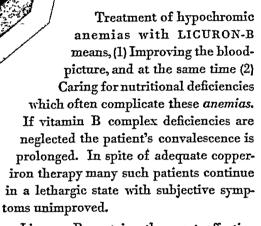

ESTABLISHES SAFE ANTIARTHRITIC EFFECT OF

ERTRON

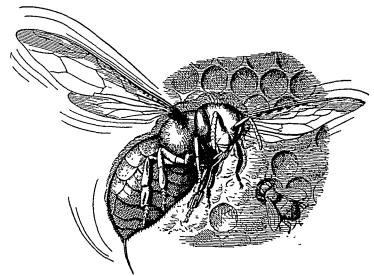

Because it is not possible to produce chronic arthritis in experimental animals comparable to that in man, the value of any antiarthritic can be determined only by studying the clinical response of patients having chronic arthritis.

The therapeutic value of ERTRON in the treatment of chronic arthritis has been determined by carefully controlled clinical investigations in large accredited hospitals, university clinics and in private practice.

Licuron-B contains the most effective therapeutic ratio of copper and iron as the basic therapy in hypochromic anemia. The content of liver in LICURON-B serves as a rich source of all the known B vitamins. This is augmented by the crystalline vitamins, thiamine, riboflavin and niacinamide in rational proportion. For literature and samples write: Lakeside Laboratories, Milwaukee, Wisconsin.

Lieuron-B

## "The honey guarded with a sting"

'Gelusil' Antacid Adsorbent has removed the "sting" from what is probably the most effective therapeutic agent for peptic ulcer, alumina gel. Heretofore, control of gastric symptoms was only too often achieved at the cost of distressing and persistent constipation. By providing a unique form of alumina, entirely resistant to gastric hydrochloric acid, 'Gelusil' Antacid Adsorbent maintains the characteristics of a true gel in the stomach and does not break down to produce astringent, constipating aluminum chloride. Nor does acid rebound and alkalosis occur to minimize the prompt and lasting relief achieved by 'Gelusil' Antacid Adsorbent.

Supplied as a gel, as well as in tablet form, 'Gelusil' Antacid Adsorbent provides stable, nonreactive aluminum hydroxide and magnesium trisilicate.... Bottles of 6 and 12 fluidounces. Boxes of 50 and 100 cellophane wrapped tablets.

## Editorial

#### What Others Think

Professor Ross A. McFarland<sup>1</sup> says, in part, as quoted by Industrial Medicine for February, 1944:

Physicians, as a group, have a wide background of knowledge in various fields, and they have spent many years of their lives in advanced study. Thus they have learned to think, and they do think, or they could not keep up in their profession. Unfortunately, however, their professional duties too often leave no time for their thinking to extend to any other fields, let alone the many others in which they have knowledge But this is a period when, probably more than ever before, it behooves all men who can think, and especially professional men, to do some earnest mentalizing with regard to certain matters of general and community and national interest. Two of these matters are history and formation to the community of these matters are history and economics—the first in respect of the kind of history this country is making, and the second as to the kind of economics our American way of life is being regimented into....

It strikes us that on the whole, physicians are too apt to think in terms of the past and to be, if anything, too little sensitive to the influences of current history; that is, to the influences of history in the making on their environment, on their future conduct, on the kinds of medical practice which will fulfill functionally the needs of today and tomorrow. Naturally this implies a study also of the changing economic picture and its influences. Some of this we touched on briefly in our January 1, 1944, issue.2

The profession has been for some time in a state of ferment. This is a healthy sign that complacency and dry rot within the

D 31 et seq. 11 to 2 Feb. 1944 p 5

profession are being sought out. In this process the physicians' own organization is being scrutinized carefully and thoughtfully. Says the Westchester Medical Bulletin:3

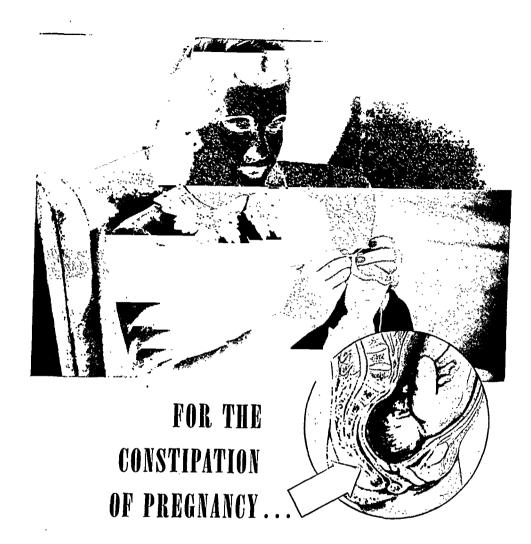

Organized Medicine.

In the Hall of Misnomers this term deserves charter membership. Medicine has an organization; but it is not organized. Usually the term is used with reference to the American Medical Association; as well speak of the American Astronomical Society as "organized astronomy"—and when, if ever, has the American Bar Association been called "organized astronomy".

The American Medical Association is an organization: by definition "an association or society." It was founded "to promote the science and art of medicine and the betterment of public health." The present organization maintains various bureaus called "councils" and publishes a number of scientific journals. Through these media the American Medical Association has contributed in no small measure to the high ethical and scientific standards of medical practice obtaining in this country today. It has been largely responsible for the continued elevation of standards of medical education and hospital service. It has consistently protected the public interest by its investigations of the claims made for different forms of therapy and therapeutic agents Through its publications it has had a powerful influence in the forward progress of scientific medicine and in the continuing education of the individual physician, whether in general or special fields. It is an organization of which any physician may be proud-of which any country might be proud

But the American Medical Association is not organized: to organize is "to become systematized or constructed into a whole of interdependent parts." No physician is a member of the A M.A. except by courtesy of his membership in his county and state society. No physician, no county society, no state society contributes to the financial support of the A.M.A. The physician may subscribe to the Journal of the American Medical Association, but he does not become a member of the A.M.A. by subscribing to the Journal, and he does not lose his membership in his county society by not subscribing to the Journal

A Medical Program for Aviation, Harvard Review (Bigines), Autumn Number, 1943

• Pressure of the fetus, lack of exercise and altered diet are factors which may induce constipation during pregnancy.

Restoration and maintenance of "habit time" is of prime importance to the patient's well-being.

Petrogalar gently, persistently, safely helps to establish "habit time" for bowel movement.

Petrogalar augments the intestinal contents by supplying unabsorbable fluid. It is evenly disseminated throughout the bowel effectively penetrating and softening hard, dry feces resulting in comfortable elimination with no straining... no discomfort.

Petrogalar is an aqueous suspension of pure mineral oil each 100 cc. of which contains 65 cc. pure mineral oil suspended in an aqueous jelly. Five types of Petrogalar provide convenient variability for individual needs.

A medicinal specialty of Petrogalar Laboratories, Inc., Chicago, Illinois, Division WYETH Incorporated.

poses—progress in bringing about a change in the public's and legislators' reactions will be of only moderate amount. In other words, if more active steps are not taken, the American Medical Association, its constituent state associations, and the latter's component county medical societies will continue to lose prestige and power in the promotion of public health work and scientific medicine. Time, in all this, is of the essence

The importance of the time element is emphasized in a recent article which appeared in the Westchester Medical Bulletin for November, published by the Medical Society of the County of Westchester, New York, and having the following title and subhead:

"THE TIME IS NOW!
What Must Be Done If the Medical
Profession Is to Fulfill Its
Fundamental Obligation to the
American People?—
A Plam Call to Action!"

Evidently the Time is Now! in the opinion of other physicians in various parts of the nation. The Hennepin County Medical Society (Minnesota) publishes in its Bulletin for January, 1944,<sup>5</sup> an article, "Growing Pains in Medicine," from which we quote:

That there is increasing discontent and dissatisfaction among physicians with conduct of the affairs of their national organization should be obvious to anyone who makes a real effort to learn the facts. This dissatisfaction is not with the scientific aspects of medicine: it is focused sharply on the public relations policy—or lack of one—of the medical guild and on the plans—or lack of them—for the distribution of medical care

That the profession is demanding and will continue to demand something other than dogged my opic defense of the status quo from its House of Delegates, officers, and employes is, or should be, apparent even to those individuals

And merely to criticize without offering something constructive in the way of a solution for the problems seen is patently unfair and unimaginative, both on the part of the present-day critics and what has been termed the "apparently self-perpetuating officials of the A.M.A..."

One's complacency should be jolted by the caustic, even beligerent criticisms of national medical leadership. One finds that leadership characterized as "top drawer impresarios and professional office holders," as an "inner sanctum. (which has) vegetated for many years in complacent cataleptic doldrums..." Very frequently, the lack of leader ship is decried. Numerous county and state organizations or groups have adopted strong resolutions calling for prompt translation into action of the expressed or widespread desires of the physicians in active practice. Regrettably, there have been hints of eccession.

The effect, if any, of all this on the "inner sanctum" is, as jet, not discernible. It is idle to attempt to dismiss this healthy interest in the conduct of medical affairs as the explosive opinions of malcontents and radicals.

contents and radicals

It is idle to charge—as one A M A official has done, off the record, of course—that the prevailing unrest and dissatisfaction is traceable to the Executive Secretary group —As a group, their loyalty and

sincerity will be attested by members of the organizations which they serve. As a group, they probably give more thought and study to the problems of medicine than most physicians. As a group, one of their tasks is to watch trends and developments and bring these to the attention of their employers for decisions on policy. Merely to blame the present unrest on this group is a palpably weak defense mechanism....

mechanism.....

To ignore this unrest would seem a dangerous tactical error, whatever opinion the "inner sanctum" may hold. This is not a passing squall which, if disregarded, will blow itself out As has been noted, already there have been broad hints of independent action to accomplish what should have been done by medicine's own organization....

To assert that those voicing this dissatisfaction are uninformed as to the real situation and entertain no constructive proposals, is plain misrepresentation . . .

Many really constructive ideas based on informed opinion are emanating from the profession in Rhode Island, California, New York, Ohio, Michigan, Connecticut, and many other states of the Union They can be found in the journals of the state societies and in the bulletins of some of the county societies, in resolutions such as those adopted at various times by the Westchester County Medical Society, the House of Delegates of the Indiana State Medical Association, the resolution of the Western State Medical Association (December 11. 1943, Salt Lake City, Utah, qv) and in a recent article in the Westchester Medical Bulletin," "The Time is Now-For a Washington Office!" Space does not permit more than a brief mention of a few of the constructive ideas and suggestions In general, the Bulletin of the Hennepin County Society4 classifies them as follows

First, state and county medical journals all over the country reflect growing discontent within the profession with the public relations policy of the A M A . . . and considering the comments of many members of Congress and other unbiased observers, it was more than startling to hear the President-elect of the A.M A declare (at the Conference of Secretaries and Editors at Chicago in November), "I believe the public relations of the (American Medical) Association are being handled perfectly I certainly think it would be a mistake to have it run in any other way ."

Second, "it is interesting to observe that an increasing number of medical journals advocate the establishment of a Washington bureau by the AMA, even at the risk of losing the latter's taxevempt status."

Third, it has been suggested that in order to make the A M A House of Delegates more responsive to the opinions of the profession, it would be desir-

<sup>\* \</sup>c] 15 \o 1, Jan , 1944, p 1 et aq

<sup>4</sup> J. Indiana M A, Dec. 1943, p 668

<sup>7</sup> Westchester Med Bull Vol XII, No 2 Feb 1944 p 7

The revenue of the Association is derived not from dues, but from the publication of its numerous medical journals. In the present-day usage of the term, how can anything be "organized" if its mem-

bers pay no dues?

But why shouldn't there be an "organized medi-cine"? Not the American Medical Association; its field of scientific endeavor is too vital to permit any dispersal of its efforts. At times it has been compelled to assume the role of spokesman for the medipelied to assume the role of spokesman for the medical profession in the absence of any other; but why shouldn't the medical profession be its own "spokesman"? Is it not time for the medical profession to admit that there is an economic—yes, and a political—aspect of medicine; that the practice of medicine is, in fact, a business as well as a profession—with economic as well as scientific problems? . . . .

From the Middle West comes to hand Volume 1, Number 1, of a new publication, the News of the Association of American Physicians and Surgeons, which has been

Established upon a sound legal foundation to give its members a positive guarantee of protection from political regimentation, and organized to take effective action in medical economics, legislation, and public relations; the Association of American Physicians and Surgeons has been incorporated, not for profit, by the members of the Lake County Medical Society, with temporary headquarters at Gary, Indiana.

The eight objectives of the Association are stated on page 1 of the issue and are here quoted for the information of our readers:

To organize all ethical physicians and surgeons of the United States and its possessions in an Association so established that its members may determine and enforce the conditions under which they will or

will not give their services.

2. To prevent participa 2. To prevent participation by a minority of its members in any plan or scheme for the distribution of medical care that is deemed by the majority to be inimical to the interests of the Association and not

conducive to the improvement of the public health

and welfare.
3. To establish by means of a national assembly of its members, in which all members have both voice and vote, a truly democratic organization of physicians and surgeons that is governed by its members and therefore actually representative of them.

Through effective action in the public interest, and under the direction of a qualified public relations counsel, to earn the good public relations and resulting public approval and support the profession

so richly deserves.

5. To move from the defensive to the offensive of problems. in the work toward the actual solution of problems in medical economics and to keep the economics of medicine under the management and control of the practitioners of medicine.

6. By means of adequate organization and competent executive action, to translate into successful accomplishment the decisions of the profession which have heretofore remained only words on the record.

7. To establish a Washington office of the Association for the execution of prompt and effective legislative action by the profession.

8. To provide a medium of expression for and actual assistance to members of the profession in the armed forces, during both the time of their military service and the period of their readjustment to civilian practice.

To the membership of the Medical Society of the State of New York, objective 4 above will appear encouraging, in that for many years the Society has successfully maintained its own Public Relations Bureau under the guidance of able public relations counsel, with notably satisfactory results. Continues the News:

The by-laws establish a Committee on Public Relations, whose duties it shall be to work toward the establishment of general public understanding of and cooperation with the profession.

At such time as this committee finds it advisable, and with the consent of the board of directors, it shall employ a full-time public relations expert, whose duty it shall be to attend all meetings of this organization and its committees, including the board of directors....

This seems to be a healthy step in the right direction, always provided that the "public relations expert" is in fact competent in his field, and if so, given a free hand. This experiment of the Lake County Medical Society will be watched with interest.

California and Western Medicine<sup>4</sup> says of the public relations of medicine in part:

During the last decade or so, it has become increasingly apparent that the medical profession has been losing influence in relation to legislation that has a direct bearing on public health activities, or on the standards and system of medical practice. Not that individual physicians are held in less regard than in days of the past, but rather, in their conjoint set-up, as represented by organized medicine-namely, national, constituent state, and component county medical societies—the profession is looked upon with more or less suspicion by many members of the United States Congress and by State and local legislative bodies. And, it may be added, likewise by thousands of citizens.

This unfortunate state of affairs is recognized by a host of physicians, many of whom are asking them-selves, "What has brought about this changed reaction of national and other legislators to organized

medicine?"

Advocating the formation of Public Health Leagues by all state medical associations, the California journal states:

It is the belief of many physicians who have inti-mate affiliations with the work and needs of organized and scientific medicine that until organizations or groups such as the Public Health League of California are brought into existence in the various States of the Union-the state groups, in turn, to form a national federation of their own, with similar pur-

# RECENT ADVANCES IN THE DIAGNOSIS AND TREATMENT OF VIRUS AND ATYPICAL PNEUMONIAS

JACOB SACHS, M.D., Brooklyn

THE evolution of our present concept of pneu-I monia marks an interesting chapter in medicine. This disease was known to the ancients and was recognized by Hippocrates and the Greek physicians. The physical findings and morbid anatomy were first classically described by Laennec in 1819. Morgagni made accurate pathologic observations at the end of the seventeenth century, and later Rokitansky differentiated the lobar and lobular types. In 1884, Fraenkel<sup>1</sup> and Weichselbaum discovered the pneumococcus as the usual causative agent of this disease. Further progress was made in 1917. Since then serotherapy, pioneered by Cole<sup>2</sup> and later advocated by Bullowa, Cooper, 4 and others, has not only become the first effective specific treatment, but has also made it possible to determine numerous type-specific pneumococci. With the advent of chemotherapy in 1938 by Whitbys and by Evans,6 epochal advances were made in the etiology, prognosis, and treatment of this disease.

We now know that pneumonia is a syndrome produced by various bacteria, viruses, and other agents. The bacterial pneumonias respond to chemotherapy and are characterized by a positive sputum, pronounced symptoms, marked lung signs, and dense x-ray shadows. The non-bacterial cases are resistant to the sulfonamides and are diagnosed by an insidious onset with grippal symptoms, negative sputum, low leukocyte count, few lung signs, and soft, patchy x-ray findings. The clinical aspects of the latter group are illustrated in the following cases.

#### Case Reports

Case 1.-A. A., a 10-year-old boy, developed fever, headache, cough, and sore throat on August 1, 1942. The temperature became normal within forty-eight hours, but rose again to 103 F. on the third day. His physician now started him on sulfadiazine, but the symptoms persisted, and I saw him in consultation on the fifth day. At this time he did not appear sick; the respirations were 24, pulse was 86, and the temperature 103.2 F. The cough was rasping and frequent, the sputum viscid and clear, and there were crackling rales at the left base. I suspected a viral pneumonia, stopped the sulfonamides, and sent the patient to the hospital. There his sputum remained clear and bacteria-free; the rough was exhausting and the fever persisted for six more days. The pulse and respirations were not accelerated and the white blood count was 8,500.

The lung signs increased and the x-rays showed a soft shadow at the left base. The patient recovered on symptomatic treatment, but sixteen days later his older sister developed a similar pneumonia at home, with ten days of fever, followed by recovery.

Case 2.—Mrs. A. S., aged 47, developed a mild viral bronchopneumonia which remained confined to the base of the left lung. The severe cough, however, persisted for three weeks after the patient's discharge from the hospital.

Case S.—Mr. B. L., aged 36, after recovering from a mild right basal viral pneumonia, developed two minor bouts of fever at home at ten-day intervals.

Case 4.-Mrs. H. K., aged 24, represented a moderately severe type, with the pneumonic process confined to one lobe. She was admitted to the Israel Zion Hospital on the eleventh day of her illness, with pronounced patchy consolidation of the left lower lobe. Before this, she had had a rather stormy course at home, with dyspnea, cyanosis, rapid pulse, severe cough, and fever spiking to 105 F. for eleven days, in spite of sulfonamide medication. sputum was obtained and the white blood count was normal. On her admission to the hospital, the leukocytes rose to 14,000 within three days; the temperature dropped to normal and the signs disappeared. The therapy consisted of steam inhalation and codeine for her cough and the sulfonamides were discontinued. The x-ray in the hospital was positive for patchy consolidation.

Case 5.—Mr. Y., 42 years old, had another moderately severe case, with fever and lung signs for ten days. On the fifth day of sulfonamide therapy, a toxic rash developed and the sulfa blood level reached 25 mg. per cent without any effect on the pneumonia. The sulfonamides were stopped and phleboclysis was administered. The fever and lung signs disappeared five days later and the patient recovered.

Case 6.-Mrs. H. R., 22 years old, had a severe virus pneumonia, which was later complicated by a secondary staphylococcic invasion, which, in turn, required continuation of chemotherapy. She entered the hospital on January 26, 1942, with signs of pneumonitis at the left base, preceded by influenzal symptoms for three days. In spite of chemotherapy, the temperature, pulse, and respiration remained high, and the lung signs increased. The leukocyte count was 8,000. The sputum, which remained negative for some time, later showed a few untyped bacteria, and the blood culture became positive for hemolytic staphylococci. On February 13, her physician contracted a nonbacterial pneumonia. This was the nineteenth day of her illness and the fifteenth day after his first exposure. At this time, when I first examined the patient, she appeared very sick, with a temperature of 105 F., marked dyspnea and cyanosis, and there

From the Department of Medicine, Israel Zion Hospital, Brooklyn.

able to limit the number of terms which any delegate

may serve..... Fourth, there is a growing conviction that the activities of the editor of the Journal of the American Medical Association should be sharply curtailed and very definitely restricted to editing that excellent publication....

Fifth, the so-called insurgents feel that while an interest in geriatrics and history is of undoubted value, the future also is of no little consequence and medicine therefore should hasten to get into step with today's social thinking, abandon its obstructionist attitude, and make positive proposals....

Sixth, it is felt that the Council on Medical Service and Public Relations, which, so this group hopes, will at last provide American medicine representation in Washington which will be persona grata, should renew the proposal of the A.M.A. for creation of a Department of Health, headed by a practicing physician as Secretary, who would be a Cabinat member.

a Cabinet member.....
Seventh, the A.M.A.'s loyal opposition stresses the urgent necessity for greater unity within the ranks of the profession itself. Many medical journals complain that state and local plans for prepaid medical care are not receiving proper support from the membership whose plans these are. Moves to establish a Washington office independent of the A.M.A. suggest a degree of disunity which is alarming. Is there anything in this, the opposition asks, that could not be corrected by a more vigorous leadership, a leadership which will actually lead, officers who will command confidence and who will contribute realistic, constructive ideas which reflect the thinking of the profession?

We present these excerpts and suggestions from numerous sources and the subjoined bibliography in an attempt, admittedly incomplete, to inform our membership of the principal symptoms of professional 'volcanism' manifesting themselves throughout the Union. We believe the physicians of the Medical Society of the State of New York are fully capable of doing their own thinking, of making their own decisions, and of making those decisions effective through their delegates and association officers. There is danger in haste, and even more in delay. Time and tide wait for no man, and the sands are running To be fully informed offers the greatest safeguard against rash decisions and the best guarantee of wise ones.

Editor's Note: As we go to press, we are advised by its chairman, Dr. Louis H. Bauer, that the A.M.A. Council on Medical Service and Public Relations has under consideration the advisability and practicability of the establishment of a Washington office for the purpose of Medical Economic Research. It is hoped that a more definite and detailed statement as to the action of the Council and of the A.M.A. governing body on this question can be published in our next issue.

monia: mild, moderate, and severe. In every case, the onset is usually insidious, with grippal symptoms, followed in three or four days by a secondary rise in temperature, marked continuous headache, intractable cough, and sweats. The pulse and respirations are not increased, the leukocyte count is low, the sputum, if present, is not hemorrhagic; the physical signs are not remarkable, but the x-ray findings are increased out of proportion to the physical findings. Later there may develop explosive rales followed by patchy areas of consolidation.

In the severer cases the pulse and respirations become more rapid and cyanosis may develop. The temperature, which usually falls on the third day, rises again on the fourth or fifth day and may spike for two or three weeks longer, unaffected by chemotherapy. The lungs later develop sticky rales, followed by physical and x-ray evidences of patchy areas involving more than one lobe. The leukocyte count, at first low, later rises to 15,000 during convalescence. Sometimes a virus pneumonia may suffer a secondary bacterial invasion. This is diagnosed by a sudden chill, higher fever, and leukocytosis, associated with an increasing number of bacteria in the sputum or sometimes by a positive blood culture.

At present, laboratory procedures cannot be applied for the early diagnosis of viral infection, but only for its later phases, or in retrospect. These procedures consist in the transmission of the disease to susceptible animals by the throat washings of the victim; or in the recovery of an increasing neutralizing antibody titer in man. The diagnosis must therefore be made by exclusion and on clinical grounds. Viral pneumonia does not respond to sulfonamides; the sputum, blood, and agglutination tests are negative; but its clinical picture is characteristic. At autopsy, the lungs show bronchopneumonic · areas consisting mostly of mononuclear cells, but no fibrin. They are deep red in color, juicy, and bacteria-free.

The bacterial pneumonias usually have an abrupt onset and a short incubation period of about one to four days. The pneumococcus is responsible for about 86 per cent of all pneumonias, 80 per cent of which are caused by types 1 to 8. The remainder are due to the streptococcus, staphylococcus, the bacillus of influenza, Friedländer and tularemia, or to a virus or a Rickettsial agent. The importance of an early bacterial diagnosis is self-evident, since both the prognosis and treatment depend upon it. In the absence of a positive sputum or blood culture, the bacterial nature of the infection, for purposes of therapy, may nevertheless be determined solely from the clinical features, which are therefore outlined below.

Pneumococcus pneumonia is characterized clinically by a sudden onset with chill, fever, pain in the chest, cough, rusty viscid sputum, cyanosis, and rapid pulse and respirations. There is a high leukocytosis with pronounced physical and x-ray findings indicative of dense consolidation.

The Friedländer infection presents a similar symptomatology, <sup>16</sup> but there is no leukocytosis and the sputum is a uniformly red, nonsticky emulsion. Abscess formation occurs frequently and the mortality is high.

Tularemia pneumonia is usually diagnosed by the agglutination test and sometimes by a positive sputum or skin test. It may occur primarily, as a result of inhalation by persons engaged in sheep shearing, or secondarily to a systemic tularemia acquired from wild rabbits or the bites of ticks and deer flies. According to Richards,<sup>17</sup> this infection responds to sulfanilamide.

The influenzal bacillus produces either a highly fatal hemorrhagic necrotizing tracheobronchitis or a pneumonia secondary to an existing virus infection. Staphylococcus and streptococcus pneumonias are usually due to secondary invasion.

#### Management

The intelligent use of specific treatment in pneumonia requires precise bacteriologic data. In all bacterial cases chemotherapy is the method of choice. It is most effective in pneumococcal infections, less so in other bacterial types, but it is ineffective in the viral or Rickettsial type. In pneumococcus infections, specific serum should be used when the sulfonamides prove to be ineffective or toxic. A combination of both serum and chemotherapy is indicated in spreading pneumonia, or in cases with bacteremia.

The procedure, therefore, is as follows: In every case of pneumonia, as soon as the clinical diagnosis is established the blood and sputum should be sent to the laboratory and chemotherapy should be instituted at once, even before the bacterial report is returned. The only absolute contraindication is a known sensitivity to the drug.18 The sulfonamides exert their maximum effects within thirty-six to forty-eight hours. Failure to respond within this time therefore suggests several possibilities, the causes for which should be ascertained and corrected. At this point, in all bacterial cases, as determined either by the laboratory findings or solely on clinical grounds, chemotherapy should be continued, provided contraindications do not exist. If the fever continues and it is found to be due to drug intoxication, medication should be stopped and resumed cautiously\_later, as required. Inwere many bubbling rales over both lungs. I thought she was now suffering from a secondary staphylococcic invasion of a primary viral pneumonia, and therefore ordered resumption of chemotherapy and oxygen. A few days later the patient was transferred to the medical ward, where the fever and lung signs continued. She was discharged against advice on February 23, 1942, and recovered later at home. The x-rays first revealed increased bronchial markings, with soft shading of the left base, and later showed a definite spread to both lungs, with patches of bronchopneumonia.

Case 7.—This case illustrated a probable secondary pneumococcus invasion. B. G., a 15-year-old boy, became sick on October 21, 1942, with fever, headache, and sore throat. The fever continued to spike to 105 F. and he developed a harsh cough, viscid white sputum, and profuse perspiration, but no lung signs; his white blood count was 9,600. On October 25, the patient had rales in the second and third left interspaces, but the sputum was reported negative. On October 26, the sputum contained a type 33 pneumococcus, considered as a possible contamination. On October 27, type 18 pneumococcus was reported to be present in the The patient was immediately hospitalized; in forty-eight hours his fever responded to sulfadiazine and he made a complete recovery three days later.

Case 8.—This case represents a Rickettsial pneumonia due to typhus. Mr. M. S., aged 56, was admitted to the hospital on July 19, 1942, as a typhus suspect, with fever, headache, rash, and a palpable spleen. Two days later, a positive Weil-Felix reaction was reported. The patient expired on July 27, 1942. During life there were no lung signs and the x-rays were negative, but autopsy revealed small bilateral juicy areas of consolidation composed characteristically of many mononuclear cells with a few scattered polymorphoruclears.

#### Discussion

Recently there has been an increasing number of patients with nonbacterial pneumonias who have given no therapeutic response to sulfona-These patients present a definite clinical mides. picture: they do not appear sick, their pulse and respirations are not accelerated, but they have fever, headache, severe cough, and positive x-ray findings, with only few physical signs. causative agent is either a virus, Rickettsial body, or Toxoplasma. Interesting descriptions of these cases have been published by Reimann and Haven,7 Kneeland and Smetena,8 Longcope,9 Finland, 10 and others. A filtrable virus has long been suspected as the causative agent of this disease, because of its contagiousness, long incubation period, characteristic pathology, and the absence of bacterial pathogens. In many cases, however, attempts to isolate a filtrable virus from the blood, secretions, and lung have failed. According to Reimann,7 this may be due

to delay in examination, weak pathogenicity of the virus, or improper selection of experimenta animals. In some cases, Stokes<sup>11</sup> and his coworkers identified a virus which was virulent for ferrets. Weir and Horsfall<sup>12</sup> have isolated a virus from some cases of pneumonitis which produced the disease in the mongoose. Adams<sup>13</sup> et al. also described a viral type of pneumonia in infants characterized by cytoplasmic inclusion bodies. The most common causative agents, however, are the viruses of influenza A and B, and the psittacine virus. They all pass through a coarse filter, have no vectors, and infect the victim directly without producing a rash.

Any viral pneumonia may become secondarily infected later in its course by the staphylococcus, streptococcus, pneumococcus, influenza bacillus, or other bacteria. This is particularly true in influenzal pneumonia, the diagnosis of which is established by the simultaneous recovery of both the bacteria and the virus (Finland). The influenzal virus is identified by its virulence for ferrets, which, in turn, produces a homologous

Psittacosis is caused by a specific virus which is transmitted from sick parrots to man, producing a highly fatal contagious pneumonia. This is associated with leukopenia and a characteristic monocytic reaction in the lungs. The virus may be recovered from the sputum of the victim and a positive complement-fixation reaction is used for diagnosis. The latter test was found positive in 4 out of 8 pneumonitis cases recently reported by Reimann<sup>15</sup> in which the patients had no history of contact with sick birds. In these cases, this was construed as evidence of infection with a psittacine-like virus of lymphogranuloma venereum, meningopneumonitis, or choriomen-

ingitis.

The Rickettsias of typhus, Rocky Mountain spotted fever, and Q fever may also produce atypical pneumonias. These bodies are transmitted by vectors and the disease in man is usually associated with a rash.

Virus pneumonia is a definite disease entity with characteristic findings. It is highly communicable by direct contact and usually has a long incubation period (about sixteen days). A sister of the patient in Case 1 and the physician who attended Case 6 contracted the disease sixteen days after contact. The following family epidemic also came under my notice. Mrs. B. D., from Brighton, transmitted viral pneumonia to her son, B. D., sixteen days after contact. Her sister, Mrs. F. A., contracted severe viral pneumonia fifteen days after nursing B. D., and she in turn transmitted the disease to her husband, A. A., eighteen days later.

Clinically, there are three types of viral pneu-

#### MÉNIÉRE'S SYNDROME—ITS MECHANISM AND MANAGEMENT

MILES ATKINSON, M.D., F.R.C.S. (Eng.), New York City

THE cause of the attacks of paroxysmal L vertigo associated with progressive deafness and tinnitus which Ménière first described and differentiated from the "cerebral apoplexies" with which they had previously been classed, has always been a mystery. In recent years, renewed interest has been shown in this condition, and several theories have been put forward to explain them, none entirely satisfactory. I do not intend to discuss these views here, but to limit myself in this paper to my own personal observations both as to mechanism and management.

#### The Mechanism

The mechanism of Ménière's syndrome, if my observations are correct, is a vascular one. The syndrome may be produced, however, by either of two different vascular disturbances, one a primary vasodilation and the other a primary vasoconstriction. Therefore if patients presenting this syndrome are to be treated logically and effectively, they must be separated first of all into their respective groups. This is done by determining their sensitivity to histamine.

The Histamine Skin Test.-Histamine is a powerful vasodilator substance. If it is introduced in minute quantity into the skin of a normal person by pricking with a needle through a drop, there ensues what Lewis has called "the triple response." First there is a dilatation of the minute vessels in the area; this is followed by a wheal; and then, provided that the sensory nerves of the area are intact, a widespread flare develops around the site of introduction. It must be emphasized that this is a normal reaction, that everybody responds to histamine injection in this way though in variable degree. To differentiate normal from abnormal response with certainty, a larger quantity must be used, and this is given by intradermal injection.

When 1/10 cc. of a 1:20,000 solution of histamine base\* is injected into the skin of a normal person, a white bleb is produced which within a few seconds is surrounded by a red ring, this repre-

Read at the Annual Meeting of the Medical Society of the

State of New York in Buffalo, May 5, 1943.
From the Ear, Nose, and Throat Service of the Third (New York University) Surgical Division, Bellevue Hospital, and the Department of Otorhinolaryngology, New York University College of Medicine.

It is important to note that the strength of the solution is determined in terms of histamine base. The different salts of histamine vary in this respect. The writer uses histamine dibydrochloride, which contains 0.57 mg of base to each 1 mg. of the salt. Dilution of 1 cc. of a 1:1,000 solution of the salt with 9 cc. of distilled water produces a solution of approximately 1:20,000 of histamine base.

senting the first part of the triple response. Very rapidly the white bleb assumes a yellowish tinge, due to the extravasation into it of serum from the dilated vessels, the second part of the response. At the same time the third part of the response begins to appear: the surrounding

For the purpose of this test, it is essential that the injection be made always in the same situation. The skin in different parts of the body gives markedly different degrees of response.1 My own practice has been to use always the volar surface of the forearm just below the elbow, and the criteria to be given refer to this location. Furthermore, the complexion of the subject must be borne in mind in judging the results, for persons of fair complexion react more strongly than those of dark.

The criteria of response to an injection given as described have been found to be as follows: The normal reaction is that in five minutes a wheal with definite edges is produced, 1/2 to 1/2 an inch in diameter, with a surrounding flare of 1 to  $1^{1}/_{2}$  inches (Fig. 1). This lasts for a further five to ten minutes. Then the wheal begins to fade into the surrounding flare, and at the end of 30 minutes, the wheal has disappeared and the flare is rapidly fading or may also have disappeared.

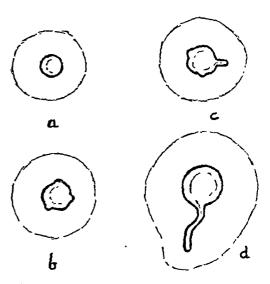

Fig. 1. Cutaneous reactions to the intradermal injection of 0.0057 mg. of histamine base. figure, a and b indicate negative reactions; c shows a doubtful reaction, and d, a positive reaction.

sufficient blood concentration demands an increased intake of sulfonamides either by mouth, vein, or rectum. In cases of overwhelming infection or bacteremia, a combination of both serum and chemotherapy should be used. Localized, confined pus requires surgery, since the sulfonamides are inactivated by the paraaminobenzoic acid produced by the pus cells. bronchial obstruction persists, it should be relieved by bronchoscopy, topical astringents, and bougies.

From the standpoint of prognosis, the severity of a pneumococcal infection is proportionate to an increase in the circulating polysaccharides, while increased resistance of the patient is determined by Sabin's agglutination test or by the Francis skin test. 19

Finally, failure of response to adequate sulfonamide therapy, unaccounted for by previously mentioned reasons, should lead one to suspect the existence of a viral pneumonia. In these cases, the drug has been ineffective all along, and should be discontinued.9 Otherwise, it may also produce toxic effects, and the patient would then be suffering from two diseases instead of one. No specific treatment has as yet been developed for primary virus pneumonia. The management is only supportive and symptomatic, consisting of oxygen, steam inhalations, expectorants, and codeine. In respiratory embarrassment due to pulmonary edema or bronchial obstruction, Baruch<sup>20</sup> recommends various forms of inhalation therapy. Oxygen, with or without helium, under pressure is used for the relief of pulmonary edema. Inhalation of vaporized solutions of adrenalin and synephrin sprayed by oxygen under pressure relieves bronchial spasm and loosens tenacious mucus. Postural drainage and aspiration of exudate may be used, especially in infants.<sup>13</sup> If the viral pneumonia is later complicated by a secondary bacterial infection, chemotherapy is then definitely indicated. 10 Throat gargles and sprays are advisable prophylactically and therapeutically.

#### Summary

The necessity for an early bacteriologic diagnosis is again emphasized, not only for typespecific pneumococci, but also for other causative agents. Use of the sulfonamides should be started in every case of pneumonia even before the laboratory report is obtained. If the characteristic curative response does not occur within forty-eight hours, the reasons therefore should be determined and the patient should be treated accordingly.

2. The differential clinical features and the treatment of the various types of pneumonia

have been discussed.

Several case reports have been presented indicative of atypical and virus pneumonia.

## CHINA HOSPITALS HAVE ODD HEATING SYSTEM

An ingenious heating system has been devised by the International Peace Hospitals in China's remote Northwest region to take the place of non-

existent furnaces. Open charcoal braziers, used by most Chinese houses in this area, generate too much dust and gas for them to be practical in hospital wards or operating rooms. So the Peace Hospitals, financially

aided by China Aid Council of United China Relief, have built special huts for wards and operating rooms. The south walls of each are made entirely of glass so as to admit the maximum of warmth from the winter sun. Under the floor of each hut is 2 brick "k'ang," or box-like stove, which, in effect, transforms the room above into a sort of oven. Virginia Medical Monthly

Horton.<sup>2</sup> For myself. I have been afraid to use this method, having been informed of two cases in which a fatal outcome was the result of giving a single large dose of histamine as a diagnostic test for gastric function, and of another in which catastrophe was narrowly averted. I regard histamine as a potentially dangerous drug, to be used with the circumspection accorded to all tissue poisons.

March 1, 1944]

The results of histamine desensitization in this group, obtained by the method described, have been eminently satisfactory. Of 14 cases which have been under observation for a sufficient time to judge of results, all have been relieved of their attacks. I hesitate to say this, for it seems too good to be true. Nevertheless, to date it is true, and I have therefore come to regard the placing of a patient in this group as indicating a prognosis as much as a diagnosis. It is interesting to note, too, that these patients regain a general sense of well-being as their treatment progresses.

On the other hand, misgroup the patient, use histamine for a patient who actually belongs to the group of vasoconstrictor patients, and not only will he not respond except for an initial period of temporary improvement due to the vasodilator effect of histamine, but he will be made more resistant to treatment along the correct vasodilator lines, as I have shown elsewhere.4 It is therefore of the first importance to be sure of a true assessment of the histamine skin test.

(b) The Vasoconstrictor Group: The large majority of Ménière patients fall into this group. Until such time as the cause or causes of vasospasm are better understood, the members of this group can only be treated empirically by vasodilator drugs. Of these, nicotinic acid has proved the most effective in my hands. It can be given over long periods of time without producing resistance to its action, and has none of the uncomfortable side-effects from fall of blood pressure which result from the administration of acetylcholine or the nitrites.

Here I would insist that it is nicotinic acid that must be used, not the amide. The acid has a vasodilator action, and it is for this reason that it is used, not because it is a vitamin. It is this vasodilator action which is essential. The amide does not produce this vasodilator action and, however effective it may be as a vitamin, it is no substitute for the acid as a vasodilator. It fails every time, as some of my patients know to their cost who have been persuaded to use the "flushless" compound. It is the flush that

The general plan is to start with injections,\*

at first a few intravenous, followed by a period of intramuscular, more or less prolonged according to response. The latter the patient can be taught to give himself. The object is to build up to the limit of individual tolerance, to maintain dosage at this maximum level until control is established, and then gradually to diminish to maintenance level. There is no hard and fast rule; each case is an individual experiment in titration.

Eventually the patient graduates from injections to oral administration, and this may have to be kept up for a long period of months or years. If a relapse or a threatening of relapse occurs, dosage must be jumped for a time, oral administration must be replaced by injections. intramuscular or even a few intravenous, and then again diminished when the acute phase has passed.

But in more detail, the routine which I adopt and which must be varied, as I have said, according to individual requirements, is somewhat as follows: A trial intramuscular injection of 25 mg. is given to determine the degree of reaction. This is followed by the same, a larger, or a smaller dose intravenously, according to reaction. It is then increased by 5 mg. at a time every second day for two weeks, to 50 mg. This is a fair average. Patients in the younger age group often take and require more; those in the older age group with less resilient vessels may not tolerate so much and must always be handled with considerable care. I cannot be too emphatic upon the necessity of cutting one's coat according to the cloth of the individual. In the early stages no one but the physician in charge can take the responsibility of judging dosage.

After the intravenous injections, the patient is taught to give himself daily intramuscular injections of the same or a gradually increasing dosage, according to circumstances. At the same time he takes 1, 2, or more tablets by mouth, usually of 50 mg. each, occasionally only 25 mg., again according to tolerance. Ultimately, after a period of time which cannot be foretold but which may often be several months, he reduces to 4, 3, 2, 0 injections a week and continues with tablets, also over a period which cannot be fore-The individual attention of the physician to the individual patient is essential to success. Nothing else will compensate for this.

Reason for Parenteral Therapy: The reason for the insistence on injection is a pragmatic one: that patients have been found to do better on this regime. Cases which have not responded to oral administration have improved and done well on parenteral. Presumably this is because in some people the drug is poorly absorbed from the stomach. A few, a very few, react satis-

The nicotinic acid for parenteral administration used in his investigation was supplied by Abbott Laboratories.

The reaction of the sensitive person is more considerable in extent and duration. At the end of five minutes the wheal measures <sup>1</sup>/<sub>2</sub> to <sup>2</sup>/<sub>4</sub> of an inch in diameter, the flare 1<sup>1</sup>/<sub>2</sub> to 2 inches. It is still present in full force for twenty minutes and is only beginning to fade after thirty minutes have elapsed. But the most important difference of all is in the development of at least one long trailing pseudopodium, often as much as 1<sup>1</sup>/<sub>2</sub> inches in length, which persists and fades with the wheal. Without this, a positive abnormal reaction cannot be adjudged.

Intermediate appearances are sometimes seen. In such a case, a second test is made with double the dose, allowing an interval of at least forty-eight hours between the two tests for the refractory period. If still no true pseudopodium appears, the test is adjudged negative.

By this means, patients with Ménière's syndrome can be divided into two groups: those giving a positive reaction, or primary vasodilator cases, and those giving a negative reaction, or primary vasoconstrictor cases. The biochemical implications of this test are still obscure. Its validity, however, has been proved by the fact that cases falling into the vasodilator group are made worse by vasodilator drugs such as acetylcholine or nicotinic acid and improved by vasoconstrictor drugs. The opposite applies to vasoconstrictor cases. For the details of the experiments which were made to determine this point, reference must be made to another paper.<sup>2</sup>

#### The Management

General Management.—I put this first because it is of as great importance as specific treatment and yet is often neglected. Almost without exception, sufferers from this condition are frightened. They have good reason to be. It can be no pleasant state to live in, to know that at any moment you may be struck by a thunderbolt of acute vertigo which renders you incapable of navigation, so that you reel about in the street or some such public place seeking for support. Add to this the concomitant distresses of pallor, sweating, nausea, vomiting, even incontinence, and it is small wonder that many patients become asocial and develop into hermits, refusing to visit their friends, to go out unaccompanied, or even to go out at all.

Others are frightened lest they have something worse than appears, and for this the neurologist has to bear his share of blame. All too often, they have been told of the possibility of a tumor, and this regardless of the fact that paroxysmal vertigo is a rare accompaniment of angle tumor, and an incomplete hearing loss associated with it rarer still. The earliest sign of an angle tumor, apart from the eighth nerve involvement, is a

diminution of the corneal reflex. Without that, I do not believe that it is justifiable so much as to moot the possibility of a tumor to the patient, still less to institute the more or less elaborate procedures necessary to rule it out. To speak of the possibility of brain tumor may seem a small matter to the trained neurologist; it means much more to the patient, who has visions of a brain operation or of losing his mind. I wish that those who so lightly speak of "tumor" could see some of the frightened results of their thoughtlessness that I see.

What Ménière patients need is reassurance, a reassurance which can legitimately be given them. They need an explanation of the cause of their distresses and to be given a confidence in the future. They need their fears dispelled. Persuade them to treatment, let them understand that gradually but with reasonable certainty their vertigo can be overcome, and half the battle is won. I say that they can legitimately be given assurance, and I think that the results of treatment after accurate grouping will show that this is so. But I cannot insist too much that each Ménière patient is an individual problem, whether from the viewpoint of general or spēcific management.

2. Specific Management.—(a) The Vasodilator Group: The members of this group comprise one in five or less of all cases—positive histamine skin tests are the exception, not the rule. When they arise, however, the prognosis is eminently good.

My own practice in this group is to desensitize to histamine by a slow method such as one uses in giving a vaccine. Following the skin test, the same dose is given subcutaneously and increased by doubling the dose until the point of reaction is reached, as shown by marked flush and headache. This dose is then repeated, after which increase of dosage is more gradual, the amount of increase depending upon individual response. Maximum dosage in my hands has never exceeded 0.5 mg. of histamine base (1 cc. of a 1:1,000 solution of histamine dihydrochloride), and some will not tolerate as much. The maximum dose is then repeated at weekly intervals for four weeks. A second course may be necessary after an interval of three to six months, and a third sometimes after a longer interval.

In the occasional instance, regular small doses of histamine are required at weekly or bimonthly intervals, to keep the patient well. I have one such case and I have been informed of one or two others. They are the exceptions.

I have had no experience of Alexander's method of rapid desensitization to histamine by intravenous infusion, as described by Shelden and

#### REPORT OF AN OUTBREAK OF GONORRHEA AT A BOYS' SCHOOL

ROBERT S. WESTPHAL, M.D., Albany

REPORTS of outprease of section in schools or similar institutions are D EPORTS of outbreaks of gonococcal ininfrequent: therefore it would seem to be of interest to report one such outbreak involving 17 out of 67 individuals in a boys' school. Also, the problem of homosexuality is generally considered as likely to exist in any place where members of one sex are living together, but the subject is not frequently discussed in the literature in common circulation. During the course of this investigation, it was discovered that the practice of rectal sodomy was apparently quite common. example, definite information was obtained which indicated that at least six such episodes involving approximately 20 boys had occurred between December 20, 1942, and January 13, 1943.

The school in question was established by a few philanthropic individuals and organizations for the rehabilitation of colored boys who had committed misdemeanors or who were underprivileged in their home environment and were of such an age as to be psychologically inadaptable to incarceration in a reformatory or other penal institution. In brief, the procedure for admission is sentence by the Children's Court of New York City. the Judge remanding the boys to the school for periods of time which may vary considerably. Among the present population of 69 boys, one has been at the school for four years and one for three but the majority for less than two years. The boys vary in age from 9 to 16 years, with only two over 14 and 58, or 84 per cent, being between 10 and 13 years of age. At the time of the outbreak the school population was 67, 2 more boys having been admitted on January 22.

As a consequence of the inaccurate memories for dates and events on the part of boys of this age and with their degree of mentality there may be slight inaccuracies in the data which are to follow, especially when they are concerned with dates. As a background to the sequence of events which led to the necessity for this investigation, it may be well to say that betweeen December 20 and 23, 1942, it is definitely known that two instances of the practice of rectal sodomy occurred, at least 8 boys being involved in these two episodes. This information is presented to indicate the fact that this practice was not unknown in the school before the outbreak of gonococcal infection. However, there had never been any previous complaints which would indicate the possibility of urethritis arising from this practice.

On December 24, 1942, 45 boys went away for a Christmas vacation. They, in addition to 2 new boys (Table 1, Cases 4 and 5), returned to the school on December 30. The routine progressed as usual until January 14, 1943, at which time the tranquility of the school was disrupted by the appearance at the infirmary of a boy complaining of urethral discharge and burning upon urination. Within a short time two more boys reported to the infirmary with similar complaints. Careful questioning by the attending physician at the school indicated a problem of rather large extent, so he applied to the State Health Department for assistance.

The facilities of a nearby city laboratory were placed at our disposal. Detailed history and physical examination forms were devised and the investigation was begun. An attempt was made to obtain a fairly complete past history from each boy, but this effort was soon discarded as relatively worthless because of the aforementioned inaccurate memories of the boys. Genitourinary and anorectal examinations were then performed on all members of the school. When an exudate was noted upon stripping the urethra, a specimen was obtained with a sterile applicator and a spread was made upon a glass slide. Another specimen was placed in a tube of broth medium for cultural examination. Similar specimens were obtained from the proctoscopic examinations. A prostatic massage was performed on all the boys, with the exception of those who had symptoms or clinical evidence of acute urethritis, and then, since in boys of this age it is difficult to obtain sufficient prostatic secretion to cause it to be discharged from the urethral opening, the patient was asked to urinate into a sterile glass container, thereby washing out of the urethra any secretion from the prostate gland as well as any pus which may have been present in the channel. Specimens were taken between 9:00 and 11:30 A.M. and were carried immediately thereafter to the laboratory, where slides were stained and examined, specimens in broth were cultured, urine samples were centrifuged, and spreads and cultures were made from the sediment. Specimens taken between 2:00 and 4:30 P.M. were treated likewise. Thus, no specimen had stood more than three hours before the laboratory procedure was begun. The cultures made on the first day were upon

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 4, 1943. Assistant District State Health Officer, New York State Department of Health, Albany.

factorily to tablets from the start, but the great majority do not. My own practice, therefore, is to insist on injections, except sometimes in mild cases when I give tablets a trial from the beginning, but always with the warning that they may not act and that injections may have to be instituted.

3. Additional Measures.—Since these observations point to Ménière's syndrome as being a manifestation of peripheral vascular disease. adjuvant measures appropriate to such a condition should be instituted at the same time. The most important of these is to place a ban upon smoking. In some instances this and no more has been sufficient to abolish attacks. proof of its efficacy is provided by the observation made for themselves by those of my patients who when they started smoking again found that the attacks recurred, and that they were again abolished by refraining. The cessation of attacks was thus proved to be a true effect, and not merely coincidental. Other general measures which are helpful are limitation of carbohydrate intake, graduated exercise, alternating warm and cool showers, an ordered and unemotional life, so far as this is possible in these tempestuous days.

It is important to explain at the beginning that this treatment produces no immediate and dramatic results. It is a slow process which leads to gradual relief, not miraculous cure. Perseverance and persistence are necessary both in patient and physician. Neither must be disheartened by setbacks, which almost invariably occur. I tell patients that when a relapse takes place, as it almost undoubtedly will, when another attack of vertigo occurs, then is the time to increase treatment, not to discard it. What they may look forward to with reasonable confidence is a gradual, even rapid diminution in the severity of the attacks and a gradual increase in the intervals between them. Ultimately after a few months or perhaps a year, vertigo and even mild dizziness will disappear. Tinnitus will often be improved, occasionally disappear or become inconspicuous, sometimes remain to plague Deafness usually rethem whatever is done. mains unchanged, though its progress is arrested. Complete failure, at least as regards attacks of vertigo, is rare in true Ménière cases.

But even when the patient is stabilized, when his vertigo is abolished or controlled by treatment, often he still experiences periods of discomfort or ill-being, periods which he recognizes as times when before treatment he would be having attacks, a sort of recurring temporary ebb

of health. What may be the explanation of this I do not know. Perhaps it is some metabolic disturbance, perhaps it is occasioned by some low-grade infection of which we have no knowledge, or perhaps by the same factor, exaggerated, which conditions the ebb and flow of health which even normal persons experience. That is a matter for the future. What I know for certain from my own experience is that in the great majority of persons relief from attacks can be envisaged with some assurance, even if absolute cure of the condition is as yet beyond our means.

The results of such considered individual treatment are encouraging. Referring only to those cases which have been under observation sufficiently long to judge of results in view of the liability to recurrence, and referring also only to attacks of vertigo and not to deafness or tinnitus, I have 49 cases at present available for assessment (end of 1942); 20 have been entirely relieved over periods of not less than six months and up to two years; 25 have been improved and are improving, which means to say that their attacks are controllable, are less in frequency and severity, or have been abolished but for insufficient time to qualify for the higher class; only 4 have been failures. These figures seem reasonably satisfactory, at least to me, and are definitely better than those obtainable in my hands by other methods. Indeed, they are better than they look, for the results have been conservatively assessed and several of the improved group seem likely to qualify in time for the relieved, judging by their progress.

#### Conclusions

1. Cases of Ménière's syndrome can be divided into two groups by means of an intradermal test of histamine sensitivity.

2. These two groups own a different physiclogic mechanism, the one primary vasodilator

the other primary vasoconstrictor.

3. Treatment, if adopted along the lines indicated in each group according to its physiclogic mechanism, has proved reasonably successful.

4. Relief of vertigo at least can be envisaged, but only by individual attention to the individual patient.

Case 35 also had active contact with Case 4 at about this time. About January 12 or 13, Case 3 had active contact with Case 4, and Case 9 had active contact with both Cases 4 and 5. Shortly after December 30, when Cases 4 and 5 were admitted to the school, an extensive episode occurred in the shower room. At this time, it was stated, Case 4 was a passive partner to 7 other boys, and Case 5 was a passive partner to 4 others, but since the 2 passive partners were not yet well-acquainted with the other members of the school, it was impossible to obtain the names of the participants. It would be reasonable to assume that there were numerous other affairs about the school between January 1 and January 13 concerning which we do not have definite information. A study of the dates of known contact in relation to dates of onset of infection as obtained from reports indicates that at least 5namely, Cases 3, 9, 10, 12, and 35-were infected by rectal contact with Cases 4 and 5.

It should be noted that the onset of symptoms in Case 15 was said to be about January 13, in spite of the fact that the patient had had contact with the girl about December 29, fifteen days before the stated date of onset. According to Pelouze, such delayed periods of incubation are probably more apparent than real. In these cases, he suggests the possibility that the disease was present in such a mild form that the patient was not aware of it until he indulged in something that acted as an exciting factor.3 The same author states further that when one's own gonococci are grown on another's mucous membrane and reacquired they usually set up an active infection.4 In view of these suggestions of Dr. Pelouze, it would seem to be within reason to assume that Case 15 could have contracted an inapparent infection from his contact with the girl, subsequently transplanting the organisms onto the rectal mucosa of Cases 4 and 5, five days after contact with the girl. This act of supplying the organisms with a new culture medium on January 3 may have increased their virulence so that when Case 15 was exposed to the activated organisms a week later, on January 10, when he again had contact with Cases 4 and 5, it would be possible that a clinical infection would result.

On the other hand, some authorities are of the opinion that an incubation period of two weeks is quite reasonable, and perhaps this would be a more simple and logical conclusion.

Cases 2, 10, and 15 had already received about 4 Gm. of sulfathiazole by mouth prior to the date of examination. In spite of this, Case 2 had positive laboratory findings.

## Control Measures Instituted

All the hoys who had a history of acute ure-

thritis, in addition to those who denied infection but had positive laboratory findings, were isolated in one large ward with one of the school counsellors as a guard. The patients with clinical evidence of proctitis were isolated in another room. Because of the possibility of the existence of symptomless carriers<sup>1,2</sup> and in order to prevent any further spread of the infection by such individuals, it was decided to administer sulfathiazole to all the members of the school. This was done with a dosage of 2 Gm. daily by mouth for ten days.

All patients who had laboratory findings to the extent of gram-negative intracellular or extracellular diplococci or simply pus in any laboratory specimen have had a minimum of three negative clinical and laboratory examinations at subsequent dates. No new cases appeared after January 15.

#### Conclusions

- 1. We have reported an outbreak of gonococcal infection in a school for colored boys in which 17, or 25.4 per cent, of the 67 individuals in the school were infected.
- 2. Aside from the initial case, all the patients having acute gonococcal urethritis were believed to have obtained their infection from contact with patients who had gonococcal proctitis.
- 3. Of the 17 cases, 6 were confirmed by laboratory tests, diagnosis was made upon history and clinical findings in 6 others, and in the remaining 5 cases by clinical evidence alone.
- 4. Two grams of sulfathiazole daily by mouth for ten days proved to be adequate for controlling the existing infections and for prevention of further spread.

#### Discussion

Dr. James H. Lade, Albany (by invitation)—An interesting aspect of institutional epidemics of gonorrhea such as this which is so ably described by Dr. Westphal is, I think, the parallel to the problem in the general population. If we disregard the esoteric mode of transmission, we have what may be termed a problem in epidemiology in vitro: a controllable population seeded to an unknown extent with a known organism. We are aware of a certain number of definite cases of infection, suspect that other symptomatic cases exist in the population, and, as the investigation proceeds, discover a number of carriers who are largely asymptomatic. The difficulties of clinical diagnosis are likely to be enhanced by the unreliability of the stained film

McLeod's medium, and the remainder were done upon a mixture of bactoproteose agar and hemoglobin solution prepared in the laboratory.

A list of the cases with their laboratory and clinical findings is presented in Table 1.

#### Comment

Since one of the oldest boys had recently left the school, 66 others who were present within the time limits of the outbreak—in addition to two new boys, making a total of 68—were examined. As indicated previously, all the boys in the school were included, especially because of the knowledge of the possible existence of symptomless gonococcus carriers.<sup>1</sup>, <sup>2</sup>

Table 1 indicates that 9 boys complained of symptoms of acute urethritis, that 3 denied the existence of symptoms but urethral exudate was found upon examination, and that in 2 who denied a history of urethritis no clinical evidence of infection was found but laboratory specimens were positive for gonococci. Therefore it could be considered that there was a total of 14 cases of genitourinary gonococcal infection. In addition to these there were 3 cases of clinical proctitis, one with gram-negative intracellular diplococci and 2 with gram-negative extracellular diplococci in the rectum. Thus, there was a total of 17 cases of gonococcal infection among 67 boys, an incidence of 25.4 per cent. Of these 17 cases, 6 were confirmed by laboratory tests, in 6

instances diagnosis was made upon history and clinical evidence, and in the remaining 5 cases on clinical evidence alone. Gram-negative extracellular diplococci were found in the urethral exudate or urinary sediment in 4 cases, 2 of these being included in the 5 cases that were diagnosed upon a basis of clinical evidence alone. Two other boys proved to have gram-negative extracellular diplococci in the rectum, but these are not included in the above rate because the bacterial flora of the rectum is so varied that it is not tenable to make a diagnosis of gonococcal proctitis simply upon demonstration of gramnegative diplococci, in the absence of any clinical evidence of infection.

#### **Epidemiology**

Considerably varied information was disclosed during the obtaining of histories from the boys. After deletion of much extraneous material the course of events seemed to be as follows: Case 15 admitted sexual contact with an older girl some time between December 25 and 30, 1942, probably about December 29. Five days later, on January 3, 1943, he committed rectal sodomy with Cases 4 and 5 acting in a passive capacity. Case 10 also had active contact with Cases 4 and 5 at about the same time. About January 10 Case 15 again had contact with Cases 4 and 5 and Case 12 had active contact with Case 4 and 5 and Case 12 had active contact with Case 35.

# SIMPLIFIED METHOD OF CONTINUOUS CAUDAL ANALGESIA IN OBSTETRICS

Julius A. Miller, M.D., New York City

ALTHOUGH it is not quite time to say that caudal analgesia in obstetrics has come of age, yet if one has used this method for delivery to any extent its benefits have become apparent. Its faults and dangers are few.

One of the most interesting aspects is the fact that with this method of delivery the mechanism of labor is definitely altered. The former mechanism of the passage of the fetus through the irregular birth channel no longer holds true. One is impressed by the relative unimportance of planes and axes and flexions and rotations.

While these factors undoubtedly do play a part in the eventual birth of the child, it is now but a minor part.

Due to the total flaccid paralysis maintained by continuous caudal analgesia, the progress of the fetal presenting part through the parturient canal is neither impeded nor aided by the soft parts.

In cases in which the fetus is in a roomy pelvis the accurate knowledge of the position is only academic; the fetal presenting part may rest on the pelvic floor in an anterior, posterior, or lateral position. There has been no resistance to its passage and therefore there may be very little or no internal rotation and very little molding.

The contractions of the uterus push the fetus to the perineum. There it rests until it is extracted with outlet forceps or is expressed by external abdominal pressure on the uterus.

The examinations to determine progress during labor present a new problem—that of the evaluation of the findings. Only with proper understanding of the paralytic condition of the pelvic soft parts and the perineal structures can the proper assay be made as to the point of descent of the presenting part in the pelvic cavity. In other methods of delivery, on rectal examination muscle and other tissue tonus, plus some resistance, voluntary and involuntary, on the part of the patient is encountered. The obstetrician unconsciously and automatically takes this into account. In caudal block analgesia the tissues through which the examination is made are soft, nonresisting, so relaxed that he is apt to imagine that the presenting part is at a much lower level than it actually is, and the cervical dilatation is therefore sometimes misjudged. In the first few cases delivered by continuous caudal analgesia I twice made the error of having the patient prepared for delivery, only to find on vaginal exam-

ination that the presenting part was still high, the cervix not completely dilated, and delivery hours away.

It may be added that cases which formerly went to ultimate extra- or intraperitoneal abdominal delivery because of an intractable, thick, undilated cervix will under caudal analgesia cause no more concern, for they will not exist. The cervix softens and easily stretches to complete dilatation. I would even suggest, when other methods are used and such a condition does arise, that caudal analgesia be tried before any other procedure is attempted to terminate the labor. A pleasant surprise will greet the obstetrician on the case.

With continuous caudal analgesia in normal cases, the woman in labor is not physically or mentally exhausted. The fetus, because there is no concerted action on it by uterine contraction, involuntary and voluntary pressure will not be damaged. Therefore, the cliché of masterly inactivity on the part of the obstetrician becomes an actuality. There is no danger of precipitated delivery with its concomitant perineal tears.

The original technic of Hingson and Edwards of caudal analgesia can be simplified by the use of a caudal needle adapter. Once in operation when the simplified method is used, any person trained in obstetrics can be entrusted to watch over the patient and to care for the continuance of the analgesia without fear of immediate or ultimate harm to mother or fetus.

This simplified technic is as follows:

Step 1: Using a 3 inch malleable needle with a Luer hub, the caudal canal is entered. Facility in getting the needle point into the canal can only be attained by constant practice, and every obstetrician should attempt caudal analgesia in all practical cases. No harm will be done if there is a failure, since other pain alleviants can be safely substituted in that event.

However, on the assumption that the needle is safely in the caudal canal, we come to Step 2: The stilet is removed and the needle hub is watched for evidence of any escaping spinal fluid. If fluid escapes, the needle is removed and the case considered not applicable for caudal analgesia. Should blood escape from the hub the stilet is reinserted and the needle gently moved to a new position. The stilet is again removed and the previous observations again made.

All conditions being favorable, we approach Step 3: The caudal adapter is fixed into the caudal and the culture as case-finding tools. We have, on the other hand, the advantage of a stable population in which therapy may be utilized at will and in which behavior is more controllable than it is outside the institutions.

Under such circumstances, the control of the outbreak is a foregone conclusion. It would certainly be possible to identify each case and carrier by repeated examinations and to render them non-infectious by the exhibition of the sulfonamides.

But if it is accepted that the examination of the stained film is unlikely to identify the gonococcus in more than 50 per cent of chronic cases, that cultures will not be positive in more than 65 per cent of clinical cases, and that the sulfonamides will fail to sterilize some 10 to 30 per cent of patients treated with a single course, the problem of complete eradication of infection from the group would require persistent and prolonged effort out of proportion to the gravity of the situation.

For the major difficulty in the control of gonorrhea, here as in general, lies in the chronic case, the gonococcus carrier. Without the aid of clinical symptoms, the screening of these individuals from a group is laborious and imperfect. But we have a therapeutic agent which is relatively innocuous in the dosages recommended for gonorrhea. It was safely exhibited in the entire group in this experiment. While such a device would be neither practicable nor desirable in the general population, we can tentatively identify some of the carriers by contact histories. When contact evidence is available, treatment may be instituted on this basis alone. If this procedure is followed, the laboratory tests may be postponed until the conclusion of therapy. I submit that these procedures must be followed if we are to control gonorrhea.

Specifically it is suggested that treatment of contacts of gonorrhea cases be initiated upon the basis of that evidence alone when laboratory data are not contradictory. This has particular application when the named contact is female. Specifically, treatment should be initiated when (1) the contact is named by more than one case with prior symptoms or subsequent onset; (2) a single contact is admitted by both parties; or (3) when clinical evidence is present in the named contact but laboratory tests are negative.

It is submitted that treatment upon the basis of this evidence is to the advantage of the contacts as well as in the interests of the public health.

#### Hotel Reservations

for the

## Annual Meeting of the Medical Society of the State of New York

Members of the Society who expect to attend the Annual Meeting May 8-11 should make reservations as soon as possible at the Hotel Pennsylvania in New York City.

Write to Mr. James H. McCabe, Manager, Hotel Pennsylvania, New York, New York. The following information concerning room accommodations and prices has been supplied by the Hotel:

Each room has a private bath—shower or tub and shower.

Room for one person per day—\$3.85, \$4.40, \$4.95, \$5.50, \$6.05, \$6.60, \$7.70.

Room for two persons per day (with double bed)—\$5.50 (shower only), \$6.05, \$6.60, \$7.15, \$7.70, \$8.25, \$8.80.

Room for two persons per day (with twin beds)—\$6.60, \$7.15, \$7.70, \$8.25, \$8.80, \$9.90.

Suite (living room, bedroom, and bath)—\$10.00, \$11.00, \$13.00, \$18.00.

For more than two persons in a double- or twin-bed room the extra charge is \$2.00 per day per person.

be prepared in a sterile packet in advance and so be ready for use at a moment's notice.

#### Comment

It cannot be emphasized too strongly that a few failures and an occasional disaster should not discredit the caudal analgesia method of delivery.

The cause of failure will always be found to be faulty technic or poor judgment. This occurs even in the simplest form of normal deliveries by any other method.

We owe a great and lasting debt to Drs. Hingson and Edwards.

> 1075 Park Avenue New York City

#### ARIZONA HAS NEW MEDICAL JOURNAL

A new state medical journal, Arizona Medicine, has just made its appearance. We quote the first editorial from the first issue—that of January— February, 1944;

#### "THE BIRTH OF Arizona Medicine

"With this issue Arizona Medicine, as official publication of the Arizona Medical Association, makes its debut among the medical journals of the other states of the nation.

"When the governors of Southwestern Medicine found it necessary to discontinue the publication of Southwestern Medicine for the duration, the Council of the State Society took the opportunity to publish a journal devoted entirely to the State of Arizona. While we regret deeply the loss of our many friends in New Mexico and El Paso, nevertheless the members of the State medical profession have long felt the need and necessity of its own journal Arizona Medicine will be published bimonthly. An attempt will be made to

reach all the physicians of the State who are in the armed forces. The curtailment of the scientific meetings of the State Society will hamper to some degree the securing of material for the pages of the journal. A letter has been written to as many of the members in the armed forces as we had addresses for, asking them for either a personal letter, or an account of their medical experiences to whatever extent they would be permitted to reveal them.

"As this first issue goes to press we have had little response so far. The problems of medical care have become such a major subject of discussion that there is scarcely an election, or a meeting of the national Congress, or the state legislatures, that new medical legislation is not proposed. It will be the policy of the editorial staff to keep the members of the State Society as fully informed as possible on the advent and progress of such legislations. The comments and criticisms of the members of the State Society will be welcomed."

#### PROBLEMS OF NUTRITION IN CHINA

China, being a vast country and composed of people of vastly different anthropological characters, religious, habits, and customs, living in widely different climates, cannot be treated as one sincle unit when problems of food consumption are single unit when problems of food consumption are studied. But one general statement can be made, and that is that the large majority of the population, even under prewar conditions, has suffered from the effects of insufficient food. According to any of the present standards of requirements, the food taken by the average Chinese has been inadequate. The most important reason for this is the low purchasing power of the average person or family. When the average income per person per year before the war (1937) was as low as 40-50 Chinese dollars (U.S. \$13-16) the purchase of an adequate amount of food becomes indeed impossible.

The inevitable consequences are general undernourishment, prevalence of deficiency diseases, lowered resistance against infections, and very much lowered expectation of life.—J. Heng Liu, M.D., and C. K. Chu, M.D., in Chinese M. J.

## DEFINITIONS FROM STUDENT NURSES' EXAMINATION PAPERS

"Adolescence is the age between puberty and adultery."

"Obesity is a surplus gone to waist."

"The spleen is an infernal organ of the body." "A skeleton is a lot of bones with the patient graped off."

"A pediatrician is a doctor who would be better off if he were a parent."

"A prostitute is a lady who has been tried and found wanton.'

"A pregnant patient is one who is heir-conditioned."—The Texas State J. M.

needle hub. This adapter is a 2 inch rubber tube closed flatly at one end, the other end having a metal needle adapter which fits securely into the hub of the caudal needle.

The injection of metycaine into the caudal canal brings us to Step 4: A 30 cc. syringe with a 1 inch, 22 gage needle is filled with 1½ per cent metycaine. The flat end of the rubber adapter is wiped with iodine or alcohol and the sterile syringe needle pushed through the flat rubber end into the lumen of the tubing. Slight negative pressure is exerted, which exhausts the air in the tubing and also determines whether there is any spinal fluid leakage. If none, 8 cc. of the metycaine solution is injected, with very little pressure needed. The syringe and the needle may now be withdrawn or left in place and held for a period of ten minutes to check on the possibility of spinal cord entry. After the ten-minute wait the remainder of the metycaine in the syringe (22 cc.) is slowly injected and the syringe with its needle is removed. The immobilizing of the caudal needle and adapter constitutes Step 5: The rubber adapter and the caudal needle hub are packed with sterile cotton so that only the flat end of the rubber tubing is left accessible. The whole is then pushed gently between the gluteal folds and strapped immovably to the buttocks. For added security a metal arch may be placed over this whole and strapped.

The parturient woman can now be made as comfortable as she desires. She may remain on her side, turn on her back, go to sleep, or read a book. The full effect of the caudal analgesia begins in five to fifteen minutes.

The time from the first full injection of 30 cc. until the necessity for the second injection arises may vary in individual women from thirty to seventy-five minutes. The need for a second and all subsequent injections is determined by the woman herself. When she complains of pain beginning in the suprapubic area the next injection is given.

As before, the flat end of the rubber adapter is made sterile with iodine or alcohol and the syringe needle is inserted through it into the lumen of the rubber tubing, and 20 to 25 cc. of metycaine is injected. At each injection negative pressure is exerted; this will determine any dangerous shift of the caudal needle, either through manipulation or the woman's movements.

As previously stated, since there is no hurry, rectal examinations can be made at infrequent intervals. The parity and the original stage of labor when the caudal analgesia was first instituted determine the frequency of these examinations. During the analgesia the woman has no urinary or intestinal urge and catheterization may

be necessary. This can be determined by routine abdominal palpation.

When the presenting part is found to be resting on the perineum and manual pressure on the abdomen when the uterus is not in contraction causes the perineum to bulge, the woman is ready to be delivered.

At this time the delivery room is made ready. The woman is placed on the delivery table, draped, and scrubbed. After these preparations have been completed one final injection of 25 cc. is made and then the caudal needle is withdrawn. The skin perforation is painted with iodine, wiped with alcohol, and the area sealed off with collodion.

For the actual delivery the use of outlet forceps is the rule. Episiotomy may or may not be necessary or may be made routine. The complete delivery with episiotomy and closure should normally take less than half an hour, though there is ample time for a longer procedure before the analgesic effects wear off. The bleeding is insignificant; the baby cries spontaneously. The placenta is expressed easily.

The repair of the episiotomy or any laceration is facilitated because of the marked reduction in bleeding. From this point on the postpartum care should be that of ordinary deliveries in the routine of the hospital or that of the attending obstetrician.

#### Summary

The simplified technic is safer and has broader uses in obstetrics:

First, because the possibility of contamination is lessened by the fewer steps and the fewer pieces of apparatus.

Second, because the dislocation of the needle from its proper position in the caudal canal is lessened because of the rigid packing and strapping, and is also safeguarded against by the metal arch covering the protruding parts.

Third, because the movements of the patient will not disturb either the procedure or the apparetus

Fourth, because the simplicity of the apparatus and the ease with which all the parts can be sterilized and made available add to the broader use of continuous caudal analgesia.

Fifth, because the simplified technic need not limit caudal analgesia only to the well-equipped hospital. The busy maternity hospital using the simple adapter method need not have dozens of pieces of complicated apparatus to autoclave, maintain, and have in readiness at all times.

Sixth, because of the economy of replacement of parts, each patient can have a new needle and adapter. This will reduce the possibility of needle breaks to the minimum. All the parts can

# THE ROLE OF PHYSICAL MEDICINE IN TREATMENT OF WAR CASUALTIES

JOSEPH A. E. SYRACUSE, M.D., Buffalo

SINCE industry, agriculture, and even the government have readjusted themselves to the present critical war emergency and, moreover, have made provision for the subsequent reconstruction period, so must the medical profession regiment its scientific resources and energies in preserving and guarding the health of the nation, and also in providing for the treatment and subsequent rehabilitation of the civilian and military war injured.

During the first World War this task fell upon medicine and surgery, although physical medicine, which was then only vaguely known and generally misunderstood, helped to ease their burden, in a somewhat probationary capacity at first. However, as the war progressed and finally ended, medicine and surgery had acquired a worthy collaborator. Physical medicine found itself being adopted by the Army and Navy Medical Corps, since its principles and practices were being introduced and generally accepted in

military and civilian hospitals.

The role of physical medicine in treating war casualties, as one may easily deduct, will be farther-reaching in its scope than in the last war. Physical medicine has made important strides forward since then, and, having weathered that probationary stage, has now become "grown up" sufficiently, I hope, to assist medicine and surgery in coping with the devastating war casualties that accompany the tremendously grim strides of modern warfare. Today's meaning of war casualties is far more comprehensive than that of yesteryear, when we pictured the return of our maimed and disabled soldier boys; the picture stopped there. Today the picture is quite differ-What happened to those boys on the battle field then is now happening in the streets and backyards of our civilized cities. Yes, I say different, because this war is more devastating and more methodically inhuman than ever. To this picture we must now add casualties received by our boys in military maneuvers, in routine military training on land, in the air, and on the We have people injured in defense plants; we have the young and old, women and children, the inevitable victims of increasing traffic accidents. Our war industries necessitate such increases in traffic and transportation of workers and materials that accidents from these sources are also increased. We shall have in addition

those injured in blackouts and in air raids. Finally, we must include as a war-born casualty that of civilian illness which will present in this war a problem far greater than in the last. In this group will be adults and children. The adults, on the one hand, especially oldsters, will suffer from lowered resistance or exhaustion, call it what you may, because of long working hours or inability to adjust themselves to the irregular eating and sleeping routine which swing shifts require. As a result, coupled with the indifferent and irresponsible attitude of single women plant workers, the rate of illness and absenteeism will become alarmingly high. Others will suffer because of so-called multiple jobs. The children, on the other hand, will suffer, first, because they are left home by working parents, to the mercy of older children, indifferent hired help, or neighbors; second, because of poor housing conditions. We therefore must conclude from this that modern war casualties will give the medical profession on both the battlefront and the home front great cause to anticipate a huge task, and surely physical medicine will be expected to do its duty, as a "grown up," side by side with medicine and surgery.

When we consider the magnitude of these war casualties, what progress, you ask, has physical medicine made toward meeting this problem? Physical medicine has made notable advances in its various fields since the last war. It is better prepared, consequently, to be of greater service in treating modern war casualties. Two distinct advances have been, first, the introduction of newer modalities, such as short wave diathermy, inductothermy, refrigeration anesthesia for surgery of the extremities, internal radiant heat unit, pavex boot, the rhythmic constrictor, low-frequency current machines, etc.; and, second, treatments such as the Kenny treatment, fever therapy, iontophoresis, electric shock therapy, newer methods of approach in the treatment of painful backs, so-called progressive relaxation. and baths such as paraffin, whirlpool, galvanic, carbon dioxide, medicated, etc. At this point we must commend the excellent cooperation given by the leading manufacturers of physical therapy equipment and their physicists in physical therapeutic research.

A further step forward is demonstrated by the fact that a larger number of hospitals, even among the smaller ones, now boast of a physical therapy department, and some have even in-

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 4, 1943.

cluded an occupational therapy section. And there is the added fact that many physical therapy schools have been founded by leading exponents-schools which have been approved and accepted by the Council of Medical Education and Hospitals for training specially qualified applicants. Surely these physical therapy technicians will provide the answer to the threatening dearth of technicians in civilian hospitals. clinics, crippled childrens' guilds, defense plants, and soon enough in Army and Navy personnel. The War Department has now created a "physiotherapy corps." Members of this corps who are graduates of approved physical therapy schools may become eligible for commissions in both the Army and the Navy.

Finally, the most vital advance that physical medicine has made is, in my opinion, its success in ingratiating itself into specialties other than its good old friend and standby, orthopaedics. Notable progress has been made into such specialties as dermatology, psychiatry, neurology, ophthalmology, gynecology, syphilology, urology, otorhinolaryngology, anesthesiology, public health, internal medicine, and industrial accident

surgery and general surgery.

As a consequence, these specialties definitely acknowledge that physical medicine has been an invaluable adjunct in the modern treatment of numerous conditions, diseases, and injuries. As a matter of record, when the division of medical sciences of the National Research Council was asked to furnish the medical departments of the United States Army and Navy with compact presentations of necessary information to be used by the medical officers of the Army and Navy in an emergency, a manual of physical therapy was prepared by the Division's Subcommittee on Physical Therapy and the Council on Physical Therapy of the American Medical Association in response to that request. This manual is concerned with a list of conditions, diseases, and injuries prevalent among war casualties, and the physical therapeutic modalities employed in the treatment thereof. The list noted includes chronic arthritis and rheumatoid conditions, sprains and dislocations, traumatic

synovitis, contusions and muscle strains, Volkmann's ischemia, bursitis, nonsuppurative tenosynovitis, fractures, peripheral nerve injuries, stiff joints, amputations, circulatory diseases of the extremities, painful feet, backache, traumatic cerebral spastic paralysis, gonococcic infections resistant to chemotherapy, dementia paralytica, cutaneous diseases, tuberculosis, and psychiatry and neurology.

Physical medicine, therefore, feels justly proud in being officially recognized by the War Department as an integral and necessary part of the medical armamentarium. It is hoped that physical medicine will leave such a lasting impression upon these medical officers in military service that they will carry home with them its principles and practice. They will thereby be able to help decongest overcrowded military hospitals. This can be done when the war is over. Because of their familiarity with physical therapy, these medical officers would be qualified to recommend and supervise the continuance of such treatments when they meet our boys again back home.

In conclusion, may I recapitulate? Modern warfare has changed the meaning of war casualties. Physical medicine was of service to medicine and surgery in the last war; it will be of greater service in this war because of the advances it has made in various fields, and because it has proved to be of invaluable service as a therapeutic adjunct to the various specialties. As a result, it is expected to aid in the treatment and final rehabilitation of all war casualties, both in the military service and at home. I should like to close by quoting a resolution from an editorial in last January's Archives of Physical Therapy, which is reassuring to both medicine and surgery:

"As physical therapeutists we resolve to perfect further the scope and efficiency of our work so it may serve the largest possible number of those disabled by active warfare, in war work, and by the accidents and diseases of every day life. With the large-scale training of medical men and technicians, we look forward to an even larger increase in the general application of physical medicine than following World War I."

### RECORD NUMBER APPLIES FOR WORKING PAPERS

"Because of the unprecedented number of highpaying wartime positions open to minors during the past year, a record-breaking total of 173,067 children applied at Health Department mercantile clinics for 'working papers' during the first eleven months alone. This figure compares with 44,293

'working paper applicants' for the entire year of 1939 and gives some indication of the steadily increasing and highly regrettable migration of New York City school children from the classroom into industry."—From the New York City Health Department Annual Report

# THE ROLE OF PHYSICAL MEDICINE IN TREATMENT OF WAR CASUALTIES

JOSEPH A. E. SYRACUSE, M.D., Buffalo

SINCE industry, agriculture, and even the government have readjusted themselves to the present critical war emergency and, moreover, have made provision for the subsequent reconstruction period, so must the medical profession regiment its scientific resources and energies in preserving and guarding the health of the nation, and also in providing for the treatment and subsequent rehabilitation of the civilian and military war injured.

During the first World War this task fell upon medicine and surgery, although physical medicine, which was then only vaguely known and generally misunderstood, helped to ease their burden, in a somewhat probationary capacity at first. However, as the war progressed and finally ended, medicine and surgery had acquired a worthy collaborator. Physical medicine found itself being adopted by the Army and Navy Medical Corps, since its principles and practices were being introduced and generally accepted in military and civilian hospitals.

The role of physical medicine in treating war casualties, as one may easily deduct, will be farther-reaching in its scope than in the last war. Physical medicine has made important strides forward since then, and, having weathered that probationary stage, has now become "grown up" sufficiently, I hope, to assist medicine and surgery in coping with the devastating war casualties that accompany the tremendously grim strides of modern warfare. Today's meaning of war casualties is far more comprehensive than that of yesteryear, when we pictured the return of our maimed and disabled soldier boys; the picture stopped there. Today the picture is quite differ-What happened to those boys on the battle field then is now happening in the streets and backyards of our civilized cities. Yes, I say different, because this war is more devastating and more methodically inhuman than ever. this picture we must now add casualties received by our boys in military maneuvers, in routine military training on land, in the air, and on the We have people injured in defense plants; we have the young and old, women and children, the inevitable victims of increasing traffic accidents. Our war industries necessitate such increases in traffic and transportation of workers and materials that accidents from these sources are also increased. We shall have in addition

those injured in blackouts and in air raids. Finally, we must include as a war-born casualty that of civilian illness which will present in this war a problem far greater than in the last. In this group will be adults and children. The adults, on the one hand, especially oldsters, will suffer from lowered resistance or exhaustion, call it what you may, because of long working hours or inability to adjust themselves to the irregular eating and sleeping routine which swing shifts require. As a result, coupled with the indifferent and irresponsible attitude of single women plant workers, the rate of illness and absenteeism will become alarmingly high. Others will suffer because of so-called multiple jobs. The children, on the other hand, will suffer, first, because they are left home by working parents, to the mercy of older children, indifferent hired help, or neighbors; second, because of poor housing conditions. We therefore must conclude from this that modern war casualties will give the medical profession on both the battlefront and the home front great cause to anticipate a huge task, and surely physical medicine will be expected to do its duty, as a "grown up," side by side with medicine and surgery.

When we consider the magnitude of these war casualties, what progress, you ask, has physical medicine made toward meeting this problem? Physical medicine has made notable advances in its various fields since the last war. It is better prepared, consequently, to be of greater service in treating modern war casualties. Two distinct advances have been, first, the introduction of newer modalities, such as short wave diathermy, inductothermy, refrigeration anesthesia for surgery of the extremities, internal radiant heat unit, pavex boot, the rhythmic constrictor, low-frequency current machines, etc.; and, second, treatments such as the Kenny treatment, fever therapy, iontophoresis, electric shock therapy, newer methods of approach in the treatment of painful backs, so-called progressive relaxation. and baths such as paraffin, whirlpool, galvanic. carbon dioxide, medicated, etc. At this point we must commend the excellent cooperation given by the leading manufacturers of physical therapy. equipment and their physicists in physical therapeutic research.

A further step forward is demonstrated by the fact that a larger number of hospitals, even among the smaller ones, now boast of a physical therapy department, and some have even in-

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 4, 1943.

sufficiently long period, will cause excessive dryness of the skin. To offset this dryness, the dermatologist has recourse to liniments, the two most commonly employed being linimentum calaminae, N.F., and linimentum calcis, N.F., or carron oil. Both of these contain 50 per cent of oil, olive and linseed respectively. Linimentum calaminae has, in addition, 16 per cent of zinc oxide, which gives a protective and cooling effect to the material. Linimentum calcis has no solid ingredient, the linseed oil being mixed with an equal volume of lime water. Another liniment frequently prescribed by the dermatologist is linimentum saponis mollis compositum, N.F., known to the laity as tincture of green soap. As it is a solution of 15 per cent soft soap and 2 per cent juniper tar in alcohol, its properties are chiefly detergent and astringent.

Oils.—Curiously enough, oils are seldom used alone to make skin less dry but are combined in solid, semisolid, or liquid water-in-oil or oilin-water emulsions. Examples of these include unguentum aquae rosae, U.S.P., and other cold creams; in these, the oil employed is chiefly mineral. This oil, as well as olive, is also of great value in softening crusts to facilitate their painless removal. Olive oil and linseed oil are the emollients in linimentum calaminae and linimentum calcis, as we have already seen. Castor oil is only infrequently used in the treatment of dermatoses but plays an important part in the preparation of certain cosmetics. Thus, it is the ingredient in brilliantines which is responsible for producing sheen on hair and also is the solvent whereby the stain (tetrabromofluorescein and allied compounds) is dispersed evenly throughout the base of lipsticks, There is room for the wider use of oily bases in the treatment of disorders of the skin of hairy areas; ointments, now commonly used for that purpose, are very difficult to remove from these sites.

Pastes and Ointments.—Medicaments pass most readily through the skin and penetrate most deeply into the underlying tissue when they are suspended in fatty bases. This is due to the fact that the layer of greasy material retains the sneat and sebum in, and prevents an escape of heat from the underlying skin, thereby causing maceration of the diseased tissues and, consequently, their closer contact with the medicament.

Pastes and ointments are materials of buttery consistency in which solids (and, in the case of some ointments, liquids, also) are mixed evenly, without emulsification, with a fat. Pastes differ from ointments in that they have at least as much solid as fat, whereas ointments seldom contain more than 20 per cent of solid, and most have much less. Pastes, therefore, are of firmer con-

sistency than ointments, penetrate less deeply, yield medicaments less readily, and are more superficial in their action. They are of particular value in the treatment of subacute eczematous conditions in which slight oozing of serum persists. The capillary action of the high proportion of solid soon brings about drying of the surface. Ointments should never be used on oozing surfaces. They possess too little capillary action and also dam up secretions.

503

The fatty bases are either petrolatum or lanolin or a mixture of both. Benzoinated lard is no longer used, as it has no special virtues and becomes rancid, and therefore irritating, somewhat readily. Petrolatum is a purified mixture of semisolid hydrocarbons obtained from petroleum. Its natural vellow to light amber color can be removed by treatment with animal charcoal. The resultant product is known as white petrolatum and has all the properties of petrolatum. It is used much more frequently than the yellow material, probably because of its more attractive color. Petrolatum, yellow or white, has two valuable properties-it does not combine with the medicaments incorporated in it and it does not become rancid. It has a disadvantage in that it will not mix with water in any proportion. renders it unsuitable for use in conditions where it is necessary to incorporate a watery material, e.g., Burow's solution, in an ointment. difficulty is overcome by the employment of adeps lanae, U.S.P., a purified, anhydrous, fatlike substance derived from the wool of sheep. It is a vellowish material composed largely of the higher solid alcohols, chiefly cholesterol, either in the free state or combined as the esters of the fatty acids present in ordinary fats. Adeps lanae, or anhydrous lanolin, mixes without separation and without losing semisolid consistency with 25-30 per cent of its weight of water, yielding an almost white product, adeps lanae hydrosus, U.S.P., or lanolin. Lanolin is employed as an ointment base either alone or mixed with an equal part of petrolatum. Anhydrous lanolin is too tenacious to be used alone and is generally softened by mixture with petrolatum.

In a search for new ointment bases, attention has recently been paid to emulsions of the cold cream type in which are incorporated compounds of a high degree of surface action which are good wetting agents and also good emulsifiers. Some of these newer bases have the valuable property of being readily removable by washing with water. However, the reports of their use have been much too meager to enable a comparison to be made between them and the older materials.

Plasters.—In U.S.P. XI adhesive plaster was defined as a mixture of rubber, resins, and waxes with one or more fillers of absorbent powder such

# Therapeutics

## CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the April 1 issue and will concern "Use and Abuse of Bed Rest."

## Basic Principles in the Use of Drugs for Local Treatment of Diseases of the Skin

Dr. McKeen Cattell: The title of the conference today is "Basic Principles in the Use of Drugs for the Local Treatment of Diseases of the Skin."

Rather than to attempt a review of the large number of formulas which the dermatologist employs, we have thought it worth while to emphasize the basic principles behind the use of some of these drugs. If we can be informed regarding the pharmacologic actions in relation to the diseases of the skin for which they are employed, then we will be in a better position to evaluate what to some of us is the somewhat mysterious composition of certain of the mixtures which are commonly employed.

Dr. Grace will open the discussion.

DR. ARTHUR W. GRACE: I wish to discuss with you the mode of action of the different types of materials employed in the treatment of diseases of the skin. Such materials are, in ascending order of cutaneous penetrability, powders, lotions, liniments, oils, pastes, ointments, and plasters.

Powders.—Powders are chiefly employed upon surfaces which are not oozing, as in contact with serum they will cake, damming up the fluid, which then becomes an excellent culture medium for the skin bacteria. They are largely used for their cooling action, in which each particle accepts heat from the inflamed skin and radiates it from many facets. The most useful powder for this purpose is talcum, a silicate of magnesium. Another valuable property of talcum is that of "slip," a term which connotes the silky feel of skin to which talcum has been applied. Talcum is chemically inert enough to be employed as a diluent for other materials employed in powder form for their special action upon the skin. Such chemicals include boric acid, sulfur, salicyclic acid, and sulfathiazole as antiseptics, alum and tannic acid as astringents, menthol and camphor as antiprurities, and ethyl aminobenzoate as an analgesic. The stearate powders, especially those of zinc and magnesium, have the useful

qualities of adhering to the skin and of repelling water, both of which are taken advantage of in preventing irritation of infants' skin by urine. Face powders owe their adhesiveness to their stearate content.

Lotions.—Lotions contain their active ingredients either in solution or suspended in water, to which may also be added, most commonly, alcohol or glycerine. In both types of lotion the same objective is sought; namely, the deposition of the therapeutic material in fine powder over and into the affected area. Alcohol is included both as a solvent and for the cooling effect produced by its ready evaporation. The higher boiling point of glycerine enables it to remain upon the skin longer than either alcohol or water and this property, coupled with its greater viscosity, helps to retain the active materials for a longer period upon the involved surface. The liquid base, by reason of its macerating effect upon the epithelium, is responsible for the superior penetrating action of the lotion, an effect which is enhanced to such a degree when the lotion is used hot that certain inflammatory dermatoses extending as deeply as the subcutaneous tissue yield to their use. Unheated lotions probably do not penetrate to a greater depth than the upper corium and so are of the greatest use in the treatment of the superficial dermatoses, which include most of the vesicular and pustular eruptions.

Lotions can be employed upon oozing as well as upon dry surfaces and are used for cooling, astringent, antipruritic, antiseptic, and analgesic purposes. Choice of the solid ingredients depends upon the nature of the condition to be treated. Generally speaking, a material that is used successfully as a powder can also be employed for the same purpose in a lotion. An exception is talcum, whose tendency to cake in the presence of water renders it inferior to zinc oxide for use in those lotions where the cooling effect of a powder is desired.

Liniments.-All lotions, when used for a

of Sarcoptes scabiei. Pediculi are killed by thick ointments of indifferent structure and their ova when attached to hairs are loosened when solvents such as xylene or benzene are applied locally.

It is important that good judgment be used not only in the kind of medicament but also in the vehicle. A sticky, ill-smelling grease is distasteful to use, particularly if the amount of skin to be treated is large. A more elegant preparation utilizing wetting agents like triethanolamine or aquaphor will be less likely left unused on the patient's shelf.

As a parting thought I should like to state my belief that most nondermatologists make the mistake of using remedies of too strong concentration. Good results in the treatment of impetigo are usually possible with the use of 2 to 4 per cent ammoniated mercury ointment. If higher concentrations are used, the affected skin may become irritated and inflamed and active treatment necessarily postponed for a period. Another common misuse of a good treatment is the application of Whitfield's ointment to an acute vesicular dermatosis. A cautious, conservative approach in prescribing for most dermatoses makes a good beginning and furthers a satisfactory outcome.

Dr. CATTELL: We will now go on to the informal part of the program. Dr. Sulzberger is here and I will ask him to open the discussion.

DR. MARION B. SULZBERGER: Dr. Grace and Dr. Lewis have so adequately covered their fields that I would like to take two slightly different approaches—and I ask premission first to be general in my remarks and after that to be more specific.

First and in general, the skin is a remarkable tissue, and one of its most remarkable features, from the point of view of our present discussion, is that it is so accessible to study—including studies in pharmacology, or the effects of drugs.

Despite the many thousands of investigations in this field, I venture to state that as yet the skin has been but inadequately utilized from the pharmacologic point of view. There are relatively few objective pharmacologic studies on cutaneous toxicity, on irritating properties, sensitizing properties, etc., or the effects on dermal nerves, blood vessels, or glands, which may be produced by many of the drugs listed in our Pharmacopeia.

In contrast to this, there are very many examples of experiments in which the skin has been used with the object of studying dermatologic reactions as indices of what has happened to the entire organism.

For example, Robert Koch's classic studies in tuberculosis would have been practically impossible without his first observations on tuber-

culous infection and reinfection of the skin, and his discovery of the specific alterations which take place in the skin's powers to react on reexposures to both tubercle bacilli and to the extracts of bacilli, i.e., Koch's tuberculin. The same is true of Schick's studies of diphtheria and of the Schick test: unless the skin had been utilized to demonstrate the acquired specific immunity to the toxin, surely Bela Schick's and von Pirquet's basic work would have been either impossible or greatly retarded.

The recent studies of Sir Thomas Lewis with histamine, and of Grant, Landis, and others of his school, really have their origin and impetus from observations on the action of histamine and trauma and cold on the skin and on the whealing of the skin; and eventually from the observation of the acquired refractoriness of the skin to whealing on repeated exposures to histamine.

In this connection I ask you also to recall that most of our understanding of the effects of physical agents was originally gained through the observation of the skin's reactions to these agents. For example most physicians still use the term "skin erythema dose" when speaking of a certain measure of x-rays: and the skin's reactions, incuding erythema, pigmentation, depilation, and atrophy, are still among the most practical biologic indices for the quantity and quality of the x-rays and beta and gamma rays delivered. And mutatis mutandis, the same remark is true of ultraviolet light rays.

These are but a few of the important fields of medicine in which the objective study of the reaction of the skin has been utilized to elucidate fundamental phenomena. But none of these examples is a true pharmacologic study upon the normal skin and upon the pathologic cutaneous processes; none is primarily a study of general therapeutic drugs by means of observations of their various cutaneous effects.

Here there is relatively little information; and relatively few drugs have been studied for their effects either upon normal skin or upon pathologically altered areas of skin. Both of these types of effects can, of course, be studied from both the objective and subjective viewpoint. We can see, feel, measure, photograph, analyze, culture, biopsy, microphotograph, spectograph, and in other ways examine the cutaneous changes we elicit with the drugs. And we can often ascertain from the human subject the subjective sensory changes drugs are producing—and all this can be done with ease and while the subject is still alive.

Our remedies used in dermatology are actually classified in these two ways; i.e., according to the subjective and according to the objective

as zinc oxide, orris root, or starch, mechanically mixed and spread evenly upon cotton cloth. The plaster mass contained about 30 per cent of rubber. In the current U.S.P. XII the ingredients of the mixture to be spread upon the fabric are not listed. Plasters form a cover much more impermeable than that obtained with pastes and ointments and so produce a greater degree of maceration of the underlying tissues than do those materials. Chemicals incorporated in the plaster mass consequently become more intimately mixed with the diseased tissue. The plaster most commonly employed in dermatology is one containing up to 40 per cent of salicylic acid and is very useful for the removal of corns and calluses.

DR. CATTELL: Dr. Lewis, will you continue? DR. Gnorge M. Lewis: In continuing the discussion, I should like to take up the reasons for employing certain types of prescriptions.

In common with other specialists, dermatologists today attempt to treat patients on an causative basis. This is not always possible; frequently we employ symptomatic and empiric treatments which from experience are known to be effective. Even when the cause of a dermatosis becomes known and is eliminated, the affected skin may require some local therapy before cure is obtained. Treatment of poison ivy requires more than removing the patient from possibility of contact with rhus toxicodendron.

Detergents are cleansing agents, of which water is the best for most skins. Other cleansing agents in common use include soap, oils, and greases. Being miscible with water, sulfonated oils are useful as cleansing substitutes when there is a soap idiosyncrasy or in instances when the irritating effect of soap is undesirable.

Applications to be used in the therapy of acute inflammations of the skin may be selected because of their antiphlogistic (soothing), cicatrizing (healing), or astringent (contacting) effects. The agents employed are usually applied in the following order, beginning with the more acute and proceeding to the others with improvement: first, wet compresses; second, lotions; third, oily suspensions; and fourth, greasy applications (pastes and ointments). For classification of topical agents see Abramowitz, E. W.: "Local Medication in Diseases of the Skin," Arch. Dermat. & Syph. 23: 644 (April) 1931.

With chronic disorders, keratolytic (desquamating, peeling), reducing (in which oxygen is removed from the tissues), and keratoplastic (stimulating) remedies are usually employed. Such a drug as chrysarobin may be used as a reducing agent but it is also stimulating and may, if used in certain concentrations, be desquamating. Other drugs used for a similar purpose,

such as mercury and sulfur, have actions on the skin comparable to the drug just mentioned. Such compounds should not be used in the presence of acute inflammation.

Antiprurities are important, since itching is the usual presenting symptom. Calamine lotion and boric acid wet compresses are soothing agents that are also frequently antipruritie in their pharmacologic action. Phenol is an example of an antipruritic whose effect is caused by a temporary anesthetizing action on the sensory nerve endings. Menthol, camphor, and alcohol are efficient antiprurities, their effect being in part at least due to their cooling action. With alcohol the cooling effect is obtained with evaporation; with the others the effect is apparent immediately upon application.

There are certain drugs which are quite useful as local antibacterial agents. The time-honored favorite employed by dermatologists is mercury. They use the drug in concentrations suitable to the skin, so that no unwanted inflammation is induced.

Mercury in the form of ammoniated mercury is a favored drug in the treatment of various streptococcic and staphylococcic infections of the skin. Various dyes and paints have also been found useful. The sulfonamides incorporated into ointments, creams, and films have come into popularity; they are of undoubted value, but apparently have a rather high index of sensitization and should not be used indiscriminately and without definite indications.

The antifungal agents employed today are for the most part unreliable and unsatisfactory. In the treatment of tinea capitis local therapy is successful when Microsporum lanosum is the causative agent. The effect of treatment is nonspecific and no particular drug is known to be lethal. Cure is obtained by mechanical epilation when ointments are rubbed in as well as by the stimulating effect on the skin, enhancing the inflammation already present with resultant defluvium. In the type of tinea capitis due to Microsporum audouini, local therapy is almost always fruitless, since the infected hairs are not loose and the application of medicaments will not produce the deep follicular inflammation required to assist in their depilation. Similarly, in fungous infections of the feet there is usually satisfactory response to the intelligent use of topical measures in the acute form of which Trichophyton gypseum is the causal agent, whereas the chronic infections due to Trichophyton purpureum are notoriously resistant and rebellious to any known therapeutic regime.

Treatment of most of the animal parasitic skin diseases is satisfactory. Sulfur, benzyl benzoate, or pyrethrum are specific in the killing did not itch, I think that dermatologic practices would suffer a sharp decline.

The practice of the dermatologist does not possess the dramatic appeal of that of many other specialists. It is not "white plague" he is combatting; it is not the eternal night of blindness; it is not the malignant horror of cancer; not the macabre, wit-destroying insanity; it is not the social scourge of syphilis; it is not the pitiful choking terror of diphtheria or the limb-twisting palsies of poliomyelitis; it is not any of these spotlighted melodramatic villains of medicine that the skin specialist is fighting. But he is nevertheless fighting a group of diseases which is probably one of the foremost causes of incapacity and inadequacy in otherwise healthy persons.

In military service in particular, one cannot fail to be impressed by the tremendous amount of disability which skin diseases produce. Over 10 per cent of all the man-days lost because of sickness in the armed forces were lost because of skin diseases. That is, out of every ten days lost (lost because of any medical or surgical disability, including losses due to venereal diseases, operations, infections, etc.) one day was lost because of skin diseases.

And these figures are based on a peacetime analysis. Under conditions of war, excluding actual battle casualties, it is probable that a still higher percentage of all disability will be due to skin disease. This is due mainly to the fact that the conditions of military life very often favor the production of the skin diseases due to crowding, moisture, sweat, friction, and other wartime exposures.

Now when we put these two facts together—first, the fact that topical treatment is still the most important part of dermatologic therapy; and second, the fact that skin diseases as a group are probably one of the most common causes of disability in human beings—they add up to the inevitable conclusion that the laws and rules and special knowledge and skills of external, topical therapy are exceedingly important for every physician.

In view of this it would, of course, be most desirable to simplify the indications, contraindications, and methods of external treatment to such a degree that they could be mastered rapidly by all physicians. Unfortunately, the attempt to do this is confronted with such difficulties that it approaches an impossibility.

Nevertheless, I said I was going to be more specific about local treatment, and I will attempt to do this in the three minutes left to me. In my opinion, the first thing to do when you see a patient with a skin disease is to consider the location of the disease in relation to the type of

topical treatment that you are going to prescribe To illustrate this dictum, I need only point out that no sane physician would think of prescribing calamine lotion to treat a disease of the hairy scalp in an ambulatory patient.

What vehicles can you use on the scalp? A question such as this surely belongs to the basic pharmacology of dermatology. The selection of the proper vehicle is part of the pharmacologic management of disease, just as much as the selection of the medicament itself or of the determination of the tolerated dose. You cannot give a woman an ointment of petrolatum-like consistency to put on the scalp liberally every day; and possibly not a man either, unless he is willing to spend a couple of hours each day trying to wash it out or is as bald as some of us. And certainly and quite comprehensibly, most women will be unable or unwilling to wash out the petrolatum or material of petrolatum-like consistency daily. Therefore, before you prescribe anything for local treatment, you must consider the location of the disease. For the scalp you choose a remedy such as a nonstaining, clear, nongreasy nondrying lotion which can be rubbed into the scalp: or, in women, a water-miscible, disappearing cream which can be rubbed in without destroying the contour and beauty and esthetic value of the coiffure. Another consideration to be borne in mind is that, whenever possible, you must not choose a medicament which will stain or discolor or which is too smelly. You have to find out what the patient and his or her environment will tolerate in the way of odors. That too is pharmacology. It is just as much pharmacology to say you cannot use medicaments which are too unpleasant to the olfactory sense as to say you cannot use a medicament which is too irritating to the gastrointestinal tract. In both instances the irritation produced will preclude the patient's further employment of the remedy.

And in speaking of tolerance and irritation. here again the location of the disease must be considered in selecting medicaments and their vehicles and concentrations. The same medicament which is well tolerated in a paste will often irritate when used in the same concentration in an ointment; or one which is tolerated in a certain concentration by the scalp will not be tolerated by the eyelids and often not by the rest of the skin. For example, 10-20 per cent ammoniated mercury in an ointment is usually not too strong for the scalp; but the neck or the face or particularly the eyelids of the same patient will often be irritated by concentrations of over 2-5 per cent. In other words, in order to prescribe topical remedies you must know their relative activity in different vehicles and bases, and also the usual relative degrees of tolerance

changes they produce. For example, in the chart which Dr. Lewis showed, you saw a heading entitled "Antiprurities." That is an entirely subjective basis for classification. It is based on how the patient's itching feels after the application of the remedy. Then on the other hand you saw on the chart such headings as "Keratolytics." That is a more or less objective criterion for classification, based on how much peeling and desquamation can be observed after application of a drug.

I do not want to tire you with further examples of how our knowledge of the effects of drugs might easily and rapidly be expanded by studies on the pharmacologic action of medicaments on the skin—but I hope that what I have outlined will suggest to you the many problems which are more accessible by this approach than by any other.

I think there is a big field beginning to open in this direction. One of the recent examples of objective, controlled, dermatopharmacologic studies were those carried out by Milberg, who I believe is here today, together with Dr. De Palma in the department of Dr. Arthur Grace at the Long Island College of Medicine. report in J. Investigative Dermat., December, 1942.) A simple technic was used to produce erythema, by measured pressure to a given skin area. Then when the norms for appearance and duration of erythema and for disappearance of erythema were established in an individual, different medicaments were applied to the skin and subsequently the erythema again produced, and the change in the time factors noted. Some very simple topical applications were found to markedly affect the times required for the development and regression of erythema. For example, it was found that simple starch poultices exerted a really tremendous "speed-up" effect upon the capacity of the blood vessels of the skin to react.

Studies of this type can be expanded and varied almost infinitely; and in this way we can soon get much accurate information regarding the effects of different local therapeutic agents upon this form of vascular cutaneous response.

Just now the pharmacology of topical therapy of the skin is really on about the same level as the pragmatic pharmacologic methods that were employed about a generation ago in general medicine. This backwardness is more the pity because the skin is so accessible to accurate pharmacologic studies.

That is not a criticism of the pharmacologist and is not a criticism of the dermatologist. It is just an unfortunate circumstance. I think that only a few people have properly approached these pharmacodermatologic problems and fewer still have received the funds, facilities, and cooperation which are necessary in order to carry out exact pharmacologic studies.

Despite this general dearth of fundamenta experimentation with the external application of remedies, the criticism is absolutely unjus that treatment of skin diseases consists of merely slapping on Lassar's paste or calamine lotion and letting it go at that. The local topica treatment of skin disease is still, I think, both a great art and a fairly accurate science, as well as the most fruitful approach to therapy in the majority of cases of skin diseases. It is through the skillful selection and application of external remedies directly to the pathologic process that the expert dermatologist grasps the unique opportunity afforded by the accessibility of the organ he is treating.

Let us take one dermatologist and have him open his practice on one side of the street, and take another dermatologist of equal training, experience, standing, personality, etc., and place his office on the other side of the street, and tell the first man, "You can treat all your skin diseases from the outside only," and the other man, "You can treat all your skin diseases from the inside only." Provided both orders were followed, the "outsider," if I may call him such, would, I am certain, soon have the inside track and soon have almost all the patients. And I say this in spite of a full realization of the advances which have been made and which are continuing to be made in the internal management of skin diseases, and in spite of the full recognition of the importance of general systemic changes and their influence upon skin diseases (and vice versa).

I am sure that most experienced dermatologists will agree with the above, and will confirm my statement that, as of today, external treatment, including radiation therapy, is still the most important part of dermatologic therapy.

But it is by no means an easy or a simple matter to carry out external treatment properly; and I think that is why most general men. and men in other fields, shy away from this problem. They don't want to have to think about it; the specialized form of prescription writing and the selection and application of external medicaments is too complex, too difficult, has too many of its own laws, is too much of a specialty in itself, for a busy general physician to become involved in these problems, particularly when there is nothing very melodramatic about most diseases of the skin and their cure.

For in dermatology most of our patients come to us because of disfigurement or because of itching. If skin diseases did not "look bad," were not disfiguring and unsightly, and if many skin if placed in lanolin with a small amount of mineral oil, than if suspended in petrolatum.

DR. WHEELER: It seems to me there are a great many beliefs of that sort which are accepted by the dermatologists as well as by other medical groups, yet when you get down to it it is very difficult to get evidence in their support.

Dr. Harry Gold: There is, of course, the fact that different types of vehicles will effect the penetration of certain agents through the skin. For example, the penetration of methyl salicylate through the skin has been studied in a variety of media: 50 per cent alcohol, oil, undiluted methyl salicylate, and then the amount of salicylate in the urine determined. The results show that the characteristics of the media greatly influence the amount absorbed.

Dr. Wheeler: But do we know, for example, that ointment would be any better than water, or as good as alcohol?

Dr. Gold: What you said about the lack of information concerning the absorption of various drugs holds, but the general fact that different media do alter the absorption of compounds through the skin is well established.

DR. WHEELER: The same thing holds when the dermatologists talk about stimulating applications. Yet we see them applying them for months to the skins of people with chronic eczema and it seems to me that usually we don't see any evidence of stimulation.

Dr. Lewis: There are two studies which have been made regarding the question of drug penetration in which serial sections have been made following the application of various medicaments in different media and it has been proved that certain types of greases carry the drug down further. I think that has been well established.

Dr. Sulzberger: Oh, yes, there is a tremendous quantity of both old and modern literature on the subject of transcutaneous penetration, with hundreds of reports and experiments, particularly during the last sixty or seventy years. Many of the modern dermatologic studies on penetration through the skin began with the study of the effects of mercurial inunctions in connection with the problems of the transcutaneous treatment of syphilis. great deal of study was given to the problems of mercurial inunction, including the questions of the best mercurial to use, the best manner and method of rubbing, and the best vehicles to use to obtain maximum penetration. Experiments of this type have always been difficult, especially when dealing with volatile substances like methyl salicylate, other essential oils, and with mercurials. The experiments must always be carefully planned and executed to rule out the absorption of the volatile material via the

respiratory tract or the swallowing of materials by the experimental animal or even by the human subject. There are many ways of measuring percutaneous absorption. One way of trying to avoid the usual difficulties is by doing biopsies of the skin after the external application, and then ascertaining, by specific staining methods and microscopic examination, the route and rate of penetration of the material applied. But there are very many technical difficulties in these experiments also. For example, one must rule out the spreading of the material by the microtome knife while cutting sections; or of spreading the material while fixing, preparing, and staining and when placing the tissues or the sections in different solutions. Despite these great difficulties, the many modern studies can be accepted as indicating that watery solutions of certain medicaments when placed on intact skin produce much less percutaneous penetration than putting on the same agents in some forms of greasy vehicles. Moreover, one can demonstrate that certain adjuvants, e.g., methyl saliculate, ethereal oils, certain wetting agentsand particularly certain newer vehicles consisting of combinations of wetting agents and solvents-all can very materially increase penetration of the embodied substances into or through the intact skin.\*

#### Summary

Dr. Solzberger: There is usually little or no dramatic appeal connected with the prevention and treatment of diseases of the skin. as a group these diseases probably account for more discomfort, more lowering of morale, and more actual illness and disability than do diseases of any other organ. Because of this fact. and also because the skin presents the most highly differentiated and most accessible tissue for direct study, the pharmacology of the skin would appear to merit more intensive—and above all more carefully integrated-study and teaching than this subject has heretofore received. The usefulness of the cutaneous tissues for study and teaching may be divided roughly into three categories:

1. The use of the skin as an indicator of the state of the individual (skin tests in diphtheria, tuberculosis, lymphogranuloma venereum, hay fever, contact dermatitis, etc.; the wheal resorption time in pre-edema; capillary microscopy; measurements of skin temperature, color, turgescence, elasticity, etc.).

2. The use of the skin for studying the biologic

Idem: Lab. & Clin Med. 28: 1305 (August, 1943); and F Herrmann, et. al.: Science 96: 451-2 (1942)

<sup>\*</sup>See Rothman, Stephen: Handbuch der normale und pathologischen Physiologie 4: 107 (1929); and Supplements, 18: S5 (1932).

of various skin areas. These are but a few examples of how location influences our prescription of both vehicle and concentration.

After due regard to location, we must consider the state of the eruption in selecting local treatment. As Dr. Lewis and Dr. Grace have pointed out, the vehicle is very important in relation to the state of the eruption to be treated. If you are treating an acutely inflamed area it is a good rule not to use an occlusive vehicle. You use wet dressings, cooling, evaporating, absorbent, and porous applications of various kinds.

According to the state, or according to the facilities for executing treatment, you prescribe compresses, baths, lotions, powders, etc. Then again, you cannot have a patient rub greases into hairy areas, or on areas subject to sweating and friction, without the danger of producing folliculitis; in many persons greases will block up the follicles and eventually produce acneform and furunculoid lesions. All of these examples are merely random selections from the literally hundreds of basic and highly specialized principles of pharmacology which must be borne in mind in applying local treatment to skin diseases.

It is only after such basic general principles have been weighed that the physician can consider the problems of the specific diagnosis of the eruption and the specific agents to be employed. And as a rule in selecting the agent to be applied, the two considerations which I have just mentioned, that is, (1) the site of the eruption, and (2) its state, are considerations much more important than the specific diagnosis.

I repeat: whether the skin lesions are torpid, whether they are highly inflamed, whether the skin is swollen, whether it is oozing, whether it is primarily or secondarily infected—these considerations of stage and state, plus the consideration of the site affected, these two determinants are usually of greater weight in selecting vehicles, active ingredients, and concentrations, than are all other considerations combined.

After the physician has applied this much logic and knowledge of the laws of external treatment, his selection of remedies becomes much like the pharmacotherapy of internal medicine; i.e., an almost purely empiric procedure based on the past experience with certain remedies in certain diseases. This leads to the classification of external remedies in the various categories which Dr. Lewis showed in his table. For example, the antibacterial substances such as mercury, dyes, sulfonamides, etc., the fungicides such as iodine, antiscabetics such as sulfur or benzoyl benzoate, these are all selected on the basis of experience, and without much knowledge

of the theories and actual mechanisms of their effects. In other words, here dermatology is just like the rest of medicine, choosing its remedies by the same methods by which quinine is chosen for treating malaria, or arsenicals for destroying trypanosomes. Nevertheless, even here the dermatologist is faced with special problems and unusual difficulties. For example, a medicament which works well in one type of vehicle will work very poorly in another. Substances which work well alone will often work better or not as well when combined with other agents; or substances ineffective or weakly effective alone or in certain combinations will prove more effective when used in conjunction with other combinations of remedies. And all of these differences in effects are often seen quite clearly and rapidly in treating that most accessible organ, the skin, and are clearly apparent to both physician and patients. This last is a happy (or respectively unhappy) circumstance which is not so generally or obviously present in treating internal organs.

And so, based on considerations and experiences such as those I have sketched, the pharmacology of external treatment takes form. And the experienced dermatologist builds up his, at first glance, seemingly unnecessarily complicated prescriptions and formulas, weighing carefully all these considerations of site and stage of the lesion, of the age and sex and other circumstances of the patient, of the physical properties of the vehicles, of compatibilities or incompatibilities, of synergistic and additive action between different agents and vehicles, and he finally selects the best combinations to produce the multivalent effects that he is trying to achieve.

DR. CATTELL: We still have time for one or two questions.

DR. C. H. WHEELER: Is there any scientific evidence that grease makes substances actually penetrate the skin more deeply than they would if an equal amount of friction were applied in watery solution or in suspension? For example, if a mercurial is rubbed on the skin with water, is there any evidence that the penetration would be less than if rubbed in with lanolin?

DR. GRACE: I do not know of any scientific evidence to support what Dr. Wheeler has said. It is well known, however, that medicaments can be made to enter the skin when they are suspended in greasy vehicles.

To cite one instance: recently experiments were performed to see how much vitamin A could be introduced through the skin in vehicles and it was found that more vitamin A, as measured by the improvement in the condition of depleted rats, could be introduced through the

# History of Medicine

#### EPONYMS IN THE HISTORY OF CANCER

JUDSON B. GILBERT, M.D., Schenectady, New York

A LTHOUGH the history of facts and theories regarding cancer is long and complicated, it is only since 1800, and mainly after 1850, that proper names have been applied to certain tu-

It is an axiom in the newspaper business that names make news. In medicine, also, the addition of biographical data to the description of a postulate, syndrome, or disease entity, rather than the assignment of a long and complicated technical phrase, adds historic interest.

My purpose here is to list in approximate chronologic order those authors whose names are attached to classic or epoch-making descriptions in the long history of cancer literature. In three instances the names of early anatomists and histologists are included, although they did not study cancer of the particular tissues they so well described.

One of the durable satisfactions of a physician's life might safely be said to be the designation of a disease after himself. It is something which he cannot do for himself, but his peers may confer the honor. It is a gift that cannot be politically maneuvered, and it consequently has the essentials of a spontaneous recognition of merit. It carves a deep, quickly recognized meaning in a language where science is respected, and often it is as distinctive as Latin or Greek terminology. The designation of eponymic terms is medicine's method of canonizing the author for all times in its literature. In a recent volume of quotations, Henry L. Mencken lists an unidentified author as saying that "the final test of fame is to have a crazy person imagine he is you." To my knowledge no physician has risen to such lofty heights with or without an attached eponym.

Emerson C. Kelly, of Albany, who has studied the complete literature of eponymic terms for several years, has considered the search for the first description of a disease entity to be futile. The following discussion will show how well-described case studies of unusual tumors were occasionally reported years before the eponymic terms were generally applied-e.g., the Krukenberg tumor of the ovary and the Meig's syndrome.

It is quite impossible to determine a reader's preferences regarding the use of eponyms. As long as some are used it saves time in selecting the literature of a given subject to have some gen-

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 5, 1943.

eral knowledge of this form of terminology. A translation of the title of a recent foreign article as "Brown-Séquard's symptom complex, complicated by Klumpke's paralysis" well illustrates the necessity of some knowledge of eponymic names. Bain has said that: "Honour belongs to the first suggestion of a discovery, if that suggestion was the means of setting someone to work to verify it; but the world must ever look upon this last operation as the crowning exploit."

Most lovers of medical lore find it pleasant to have the history of their favorite science recalled to mind by terms that embody the names of the masters of medicine. Many eponyms cannot be improved upon by the substitution of any arbitrary combination of Greek or Latin derivatives in place of the name of the discoverer.

German medical students and hospital assistants have been apt to coin eponymic terms in honor of the Geheimrat professor-either as a subtle form of flattery or in recognition of a solid achievement. French literature presents some examples of this same tendency.

A report from the London Lancet of July 29, 1837, discourses as follows on: "Priority! What a magic word!-as dear to the soi-disant discoverer, as is honour to the maiden, glory to the soldier, or freedom to the patriot's heart. A celebrated historian has remarked, that of all civil commotions, the most sanguinary and inveterate are those which arise in consequence of religious dissentions. Even thus is it with the feuds of 'discoverers.' Priority is a hidden treasure, suddenly brought to light, upon which every adventurer falls, each determined to carry off, at least a portion of, the booty, if he fails to appropriate the whole. Hence, the moment that a new fact is announced,-a fresh discovery in medical science is proclaimed, and a troop of foragers are on the qui vive, like passengers in a street, when a cry of 'Pickpocket! Stop, thief!' is raised. The more prudent consult their memories, or their notebooks, and there find record, at all events of 'the germ' of the alleged discovery. while some literary jackall discharges from the venthole of his empty noodle the only idea that was ever contained in that cavity, and, with a pertinacity which is peculiar to his class, insists on its identity with the fact announced, declaring that it was familiar to him from his childhood. or handed down to him, perhaps, from a long line of illustrious ancestors. The quarrel once serieffects and the effector mechanisms and effector organs in relationship to chemical and physical agents (histamine, choline, adrenalin, pilocarpine, cold, heat, stroking, pressure, tension, etc., in relation to axon reflexes, vascular, sudomotor and pilomotor responses; x-rays, radium, and light in relation to erythema, vesication, pigmentation, depilation, and carcinogenesis; the effects of vesicants, allergens, carcinogenic substances, of micro-organisms, of hormones, of vitamins, and so forth).

3. The use of the reactions of both normal and and pathologic skin for the study and evaluation of agents to be used in treating skin diseases.

The last category is still largely on an empiric basis and the local therapy of skin diseases is therefore still based upon a combination of the experiences of others plus an elaboration of personal judgment and observations rather than on laboratory and experimental data.

Nevertheless, local and external treatment is at present by far the most effective form of management of cutaneous disorders. Moreover, if physicians could treat ulcers or tumors of the gastrointestinal tract, or certain lesions of the brain, lungs, kidneys, heart, or other viscus as early and as directly as they are able to treat cutaneous lesions, they would undoubtedly be able to scotch incipient disorders in the viscera as regularly as they do those of the skin.

In selecting dermatologic remedies for external application, the practical considerations of age, sex, occupation, duties, and economic and social status of the patient must often be paramount.

The exact site of the lesions is another prime consideration influencing the selection of remedies (hairy or nonhairy, covered or exposed, subject to friction or maceration or not, etc.).

A third and most weighty consideration is the state and stage of the skin disease (acutely inflamed, swollen, oozing, or chronic, dry, scaly, thickened, etc.).

The choice of vehicle is often more important than the choice of so-called "active" ingredi-

ents.

And above all the physician must have perfect knowledge of the properties of each medicament he prescribes: its color, consistency, odor, and packaging; how it is to be put on, how it will stay on, how it is to be removed; its expected effects and possible by-effects, including any staining, unsightliness, discomfort, and allergic reactions it may occasion. Prescriptions given without explicit directions and warnings to the patient will either be used incorrectly or will soon be relegated to the sink, trash basket, or bathroom shelf.

As experimental studies and the teaching of pharmacology of the skin gain their proper status and as our knowledge of this subject increases. dermatologic therapy will undoubtedly increase in effectiveness. But even today the science (and art) of local treatment is, to say the least, as fully developed as are other branches of therapeutics.

Dermatology has its own well-established rules, based on a great wealth of careful clinical observations. The physician who knows these rules and who lege artis and skillfully selects and applies the various available bandages, compresses, lotions, tinctures, pastes, ointments, plasters, baths, splints, zinc gelatin dressings, as well as physical measures such as cold, heat, electrolysis, x-ray, radium, and ultraviolet rays, each in its proper place and in correct combination or sequence, will bring relief in most cases of skin diseases.

#### HEALTH ASSOCIATION RE-ELECTS AMBERSON

Dr. J. Burns Amberson was re-elected president of the New York Tuberculo-is and Health Association at the annual meeting of its Board of Directors held on January 25.

Re-elected also to office for the year were Bailey B. Burritt, first vice-president; Dr. Edwin P. Maynard, Jr., second vice-president; Daniel Paul Higgins, secretary, and Raymond Atkin, treasurer. Those elected to the Executive Committee of the Association include Mr. Atkin, Mr. Burritt, Dr. E. H. L. Corwin, Dr. Kendall Emerson, Dr. Oswald R. Jones, Dr. Maynard, Dr. James Alexander Miller, Mrs. Ruth Logan Roberts, Dr. I. Ogden Woodruff, and Dr. Amberson, ex officio.

Woodruff, and Dr. Amberson, ex officio.
Alfred C. Howell, Dr. H. McLeod Riggins, and
Winthrop A. Wood were elected to serve as representatives of the Association on the Council of

the Tuberculosis and Health Association of Greater New York, which includes the Brooklyn and Queensboro Tuberculosis and Health Associations Dr. Amberson and Frank Kiernan, Executive Director, will serve as ex officio representatives to the Council.

Dr. C. C. Pierce, chairman of the Social Hygiene Committee of the Association, was elected a member of the Board of Directors to serve until 1947. Those whose terms expired this year and who were re-elected to serve also until 1947 include: Dr. Amberson, Mr. Burritt, Dr. Emerson, Dr. Miller, Dr. B. S. Oppenheimer, Dr. Edward C. Podvin, Dr. Riggins, D. Kenneth Rose, Mrs. Alfred Shriver, Dr. Wilson G. Smillie, Dr. Ernest L. Stebhins, Benjamin Strong, Dr. Grant Thorburn, Mr. Wood, and Dr. Woodruff.

written before cells were even known, before cellular pathology was established and blood examinations were made. Personally, Hodgkin was an eccentric and unhappy Quaker. His total writings numbered only 49, fewer by many than those of the great Paget, who was more a man of affairs and in every way more successful.

In the first series of the Index Catalogue up to the year 1887 there were 58 references to the eponym Hodgkin's disease under the general heading lymphadenoma. The first use of the proper name of Hodgkin was made by Samuel Wilks in the Guy's Hospital Report of 1865. In 1856 Wilks had preceded Hodgkin with a paper on "Cases of Lardaceous Disease and Some Allied Affections." These cases were described without knowledge of Hodgkin's previous report, and he lamented the fact that Hodgkin "did not affix a distinctive name to the disease." This defect he himself remedied by applying the eponym of Hodgkin's disease, perhaps for chauvanistic reasons, and in honor of Guy's Hospital. Hodgkin was curator of the Pathological Museum at Guy's Hospital when he collected his material, and Wilks followed a rather distinctive English custom of compiling and correlating interesting cases, which has survived to the present time. While the more recent collections of this sort have not all been of such great importance, still they are of considerable value, as patiently collected and described series of unusual pathologic conditions.

The first American reference was by T. J. Black in the American Journal of the Medical Sciences of 1868, a journal at that time already in its fifty-fifth volume. The first thesis to bear this eponym in the title was written by F. Menne in a doctor's dissertation at Wuerzburg in 1878, while G. A. Wunderlich used it in a German magazine article in 1866. In France the eponym was first used in a paper by Severt in 1872; while in Italy, E. de Renzi and P. Penta used it in articles published at Naples in 1884.

Emile Adolphe Bonfils in 1857 also wrote a 25-page study on this subject, and the French have honored him by identifying this disease with his name. The great French clinician Armand Trousseau (1801–1867) is also eponymically cited in "Trousseau's Adenitis in Pseudoleukemia."

P. K. Pel and W. Ebstein in 1887, in the Berliner Klinische Wochenschrift, described 3 and 10 cases, respectively, of phases of this disease characterized by an irregular febrile course. This peculiarity has since been identified by the combined eponym of the Pel-Ebstein syndrome.

A most modern account of the cellular structure of this disease was given by A. Dietrich in 1896 Because of the serious omission of descriptive plates this worth-while contribution never received its due award.

Histologic advances in the study of Hodgkin's disease were made by Carl Sternberg (1889) in the presentation of 15 cases under the title "A Particular Form of Widely Scattered Tuberculosis of the Lymphatic Apparatus Presenting the Picture of Pseudoleukemia." Four years later Dorothy M. Reed (1902), an investigator at Johns Hopkins, made an exhaustive study of 8 cases in a 64-page paper. In 1940 George W. Jones, in a finely critical survey of the question of histology, concludes that Dorothy Reed is the one most worthy of eponymic commemoration wherever the "characteristic cells" are found in the lymphoid tissues of Hodgkin's disease.

Nathan E. Brill and coworkers in 1925 described an unusual form of abdominal Hodgkin's disease. Two years later Douglas Symmers of Bellevue Hospital described the pathologic findings on the basis of 3 cases.

M. H. Gordon, in 1932, described an animal test in which an emulsion of a suspected gland is injected intracranially into a rabbit. After two to six days' incubation, microscopic examination is said to give a characteristic appearance. This test has been checked and criticized by others, but apparently it has some merit in differential diagnosis, for it was eponymized by C. E. van Rooyen in 1933.

In discussing the lymphomatous diseases (or the so-called lymphoblastomas) Edward B. Krumbhaar (1936) has given his preference to certain eponymic names that are noncommittal as to causation—at least until a cause for the disease based on adequate evidence is forthcoming. He states correctly that the great difficulty is that any designation that approaches accuracy becomes an unwieldly description, not a term.

#### Mammary Gland

At the advanced age of 60, Sir James Paget (1814–1899), the great English pathologist and surgeon, first described "the diseases of the mammary areola preceding cancer of the mammary gland." This paper was his one hundred and eleventh medical publication, his grand total on many diverse subjects being 175. He is also known eponymically for four other disease entities and one drug mixture. His paper on breast cancer was based on a study of 15 cases, which were not separately described, but were rather presented as a masterly, concise summary in only three short pages.

Following the original description of Paget's disease of the breast in 1874, the *Index Catalogue* of 1888 collected nineteen references, twelve of them using Paget's name in the title. The first to give it an eponymic character was T. McAnder-

ously aroused, the partizans of each claimant forthwith rally round their principal, and the battle becomes general. Hard words are interchanged, and men who have hitherto been as 'honourable' as Brutus, suddenly find themselves arraigned as thieves. The learned are convinced of profound ignorance; men of veracity are shewn to be false witnesses; social order is sacrificed to personal vanity; and friendship changes into hatred, and esteem into contempt." This original of 1837 contains some broad Rabelaisian satire, which would hardly bear complete reprinting in the Lancet of today.

In 1877, the immortal Hermann von Helmholtz delivered his famous address on "Thought and Medicine," at which time he commented that it was thirty-five years (1842) since he had read a paper before a similar audience on the "Operation of Venal Tumours." Apparently this was an inaugural dissertation, and he admitted that at the time of delivery he had never seen a tumor cut, and the subject matter of his lecture was merely compiled from books. In this interesting lecture of 1877 he comments entertainingly on the question of priority: "To find superficial resemblances is easy; it is amusing in society, and witty thoughts soon procure for their author the name of a clever man. Among the great number of such ideas, there must be some which are ultimately found to be partially or wholly correct; it would be a stroke of skill always to guess falsely. In such a happy chance a man can loudly claim his priority for the discovery; if otherwise, a lucky oblivion conceals the false conclusions. The adherents of such a process are glad to certify the value of a first thought. Conscientious workers who are shy at bringing their thoughts before the public before they have tested them in all directions, solved all doubts, and have firmly established the proof, these are at a decided disadvantage. To settle the present kind of questions of priority, only by the date of their first publication, and without considering the ripeness of the research, has seriously favored this mischief.

"In the hundreds of books and pamphlets which are every year published about...carcinoma, all the most refined shades of possible hypotheses are exhausted, and among these there must necessarily be many fragments of the correct theory. But who knows how to find them?"

#### Nobel Prize Winners

There have been a total of thirty-four Nobel Prize winners in medicine between the time of Emil von Behring (1901) and the last prize to Gerhard Domagk in 1939. It is rather surprising that only two of these medical Nobel Prize winners have been honored for work on cancer.

Johannes Fibiger (1867-1928), professor of pathology at Copenhagen, was so honored in 1926, thirteen years after publication of his paper concerning the relation of a Nematode worm to cancer of the rat's stomach. After five years of laborious work he succeeded in proving that this worm, during its evolution, used a particular type of cockroach as an intermediate host. He was able to produce gastric papillomata, and in some instances true cancer, by feeding rats these specific cockroaches. It is of casual interest that he published this observation in three different journals within a year of 1913. It is also noteworthy that he died of intestinal cancer on January 30, 1928, two years after being awarded his delayed Nobel Prize.

Otto Heinrich Warburg (1883—) was also honored by a Nobel Prize in 1931 for the discovery of the function of the reproduction ferment of cancer cells. His first paper in a medical journal was published in 1925 and was followed by a monograph a year later.

#### Special Tests

The Fourth Series of the Surgeon General's Index Catalogue has indexed special cancer tests in groups and under eponymic names. For example, cytolytic tests are listed by three workers; endocrine tests once; flocculation tests seven times and hemoclastic tests (alimentary leukopenia) are listed four times. Many of these have arrived at eponymic proportions in a span of only a few years. Their importance has been recognized by the editors in a special listing under the respective authors' names. As this list is long, and since none have been completely accepted, further details are omitted here.

The two most readily recalled eponymic terms are probably Hodgkin's disease and Paget's disease, the latter referring to breast cancer and not to his second eponym on osteitis deformans. Because of their popularity they will be discussed in greater detail.

#### Lymphomatous Diseases

In the early part of the nineteenth century Thomas Hodgkin, a scholarly English physician (1798–1866), at the early age of 34, published the description of 7 personal cases, together with 7 collected from his friends, describing "Morbid Appearances of the Absorbent Glands and Spleen" in 1832. This description of a new disease was his ninth medical publication. The original paper was printed without illustration and is reproduced in its entirety in the Medical Classics edited by E. C. Kelly, who said in effect that we must not wonder that Hodgkin knew so little, but marvel that he knew so much when we realize that the original description was

of the Royal College of Surgeons of England, Vol. 1, 1846. The autopsy of a 49-year-old woman revealed scirrhus cancer of the stomach with bilateral involvement of the ovaries, which formed rounded oval masses about two inches in diameter. This is undoubtedly one of the earliest reports of this unusual metastatic tumor.

Under the directorship of Eugen Albrecht at Frankfurt a. M., Fritz Brenner wrote his doctor's thesis in 1907, at the age of 30, describing 3 cases under the title of "oophoroma folliculare." This thesis was promptly republished in the Frankfurt Zeitschrift für Pathologie. The tumor has a distinct histologic appearance, yet strangely enough the thesis contains no plates. J. Varangot, of France, in 1938 called attention to the nature and significance of the grooved nuclei of Brenner tumors, which R. Meyer had seen, but not emphasized, as early as 1932. Here again, as in the Krukenberg tumors with signet ring cells, the microscopic appearance is distinctive. Recent contributors on this subject give Varangot credit for proper emphasis on this point.

In 1937 Joe Vincent Meigs and J. W. Cass reported 7 cases of a syndrome characterized by a fibroma of the ovary with ascites and hydrothorax in a 37-page paper. The difficulty of explaining how fluid extends from the abdomen to the chest is a most important and intriguing question. It is of historic interest that C. J. Cullingworth described in the London Obstetrical Transactions of 1879 fibromata of both ovaries found at autopsy, which undoubtedly was one of the first descriptions of this complex disease entity.

Cervix.—Cancer of the uterine cervix has been one of the greatest fields of discussion in gynecology for many years. The cervix is an organ where direct visual examination can be made, yet early diagnosis often fails to approach the attainable maximum of accuracy. In 1872 Otto Spiegelberg (1830-1891) is said to have described a sign of cancer consisting of the recognition of a feeling of friction conveyed to the finger in digital examination of the uterine cervix. It seems a time quite remote when such a sign could be of much importance, and yet it has attained eponymic mention. Walter Schiller in 1928 first described a simple visual test using Gram's iodine solution to delineate suspected cancer tissue. This is followed by a scraping biopsy and regular histologic study.

Skin.—Arthur Jacob, in a small Irish publication in 1827, described an unusual ulcer of the eyelids, which was promptly recognized as a form of cancer, the rodent ulcer. This journal is elusive and has not been seen in the original, but subsequent authors used the term Jacob's ulcer after his publication. In 1872, at the age of 53, Moritz Kaposi described a rare and highly malignant

disease known as idiopathic multiple pigment sarcoma of the skin.

Henry A. G. Brooke, an Englishman, in 1892 discussed 4 cases of characteristic tumors of the skin, now known as adenoid cystic epithelioma. The original was extensively illustrated and included a fine color plate. Basal cell cancer of the skin was discussed exhaustively in a monograph in 1903 by Edmund Krompecher, about seventy-five years after Jacob's report.

John Templeton Bowen (1857— ), an American dermatologist, in 1912 described 2 cases of precancerous dermatoses demonstrated in chronic atypical proliferations, and in 1924 Paul Masson very clearly described 2 cases of neuromyomatous glomus tumors, illustrated by eight plates, one in trichrome stain. Since then many authors have referred to similar tumors as Masson's glomus tumor.

Other tumors of the skin associated with eponyms were described by Brown-Pearce, Malherbe, and Spiegler.

Lung.—Henry K. Pancoast, a distinguished radiologist of Philadelphia, emphasized in 1924 the importance of careful roentgenologic investigation of apical chest tumors and discussed 5 cases. An associate reviewed the earlier related literature since 1869, but the description of Pancoast is so clear-cut that this eponym is justly deserved and much used today in all discussion of pulmonary neoplasms.

Nasopharynx.—Alexander Schmincke in 1921 described 5 cases of lympho-epithelioma of Waldeyer's ring of lymphatic tissue of the nasopharynx in a paper of 10 pages. This tumor tends to metastasize widely and is fairly sensitive to irradiation therapy in its early stages. In 1832, Sir Felix Semon (1849–1921), a German laryngologist in England, described a sign of malignant disease of the larynx that causes impairment of the mobility or fixation of the vocal cords.

In the seventeenth century a German physician, Conrad Viktor Schneider (1610-1680), described the membrane which lines the nasal cavities and paranasal sinuses. Tumors arising from these structures are apt to be characteristic histologically and are generally radiosensitive.

Thyroid.—Karl Hürthle (1860— ), a German biologist and surgeon, in 1894 described characteristic cells of the thyroid gland which reproduce the unusual tissue when the thyroid is involved by neoplasm.

Bone-Multiple Myeloma.—The findings of a new substance occurring in the urine of a patient with mollities ossium were presented by Henry Bence-Jones (1813-1873) before the Royal Society of London on April 22, 1847. The article appeared one year later in the Society's

son in 1882, who reported in the Glasgow Medical The first German thesis was by A. Journal. Hanser, and was given at Heidelberg in 1886. Ten years after its introduction, George E. De Schweinitz reported the first American case in the Philadelphia Medical News of 1884. Apparently the first French thesis was by P. Fisse of Toulouse in 1897. In the meantime, a report by Chalot in 1882-1883 was the first in the French magazine literature. By 1906 the Second Series of the Index Catalogue listed seventy-seven papers under the heading "Nipples (Eczema of)-Paget's Disease," including two French theses. In about thirty years approximately one hundred papers had appeared which followed up the original observation of Paget and used his name in the title of the papers.

#### Cancer of the Genitourinary System

Kidney.—The early history of kidney cancer dates back to the time of Pierre François Olive Rayer (1793-1867), whose three-volume work in 1839-1841 was the first comprehensive study in any language, and the accompanying atlas illustrated renal cancer in all its various gross appearances. In 1885 Robin's careful histologic studies traced the origin of cancer of the kidney from the epithelium to the urinary tubules. Unfortunately this paper included no illustrations and therefore failed to be as important to the author's contemporaries as it appears to us in retrospect. Paul Grawitz, in 1883, described a tumor of the kidney which appears to arise from adrenal rests and promptly started a vast conflicting literature on this subject, which is not settled even today. Although K. J. Eberth recognized the unique character of a mixed tumor in a child, the eponymic honor goes to Max Wilms, who in 1899 so clearly described the entire group of mixed tumors that he is generally given the credit. monograph, however, contains only three reports of tumors in children, and one of these is merely the description of a specimen.

Adrenal Gland.—Malignant tumors of the adrenal gland have been described by William Pepper, an American, in 1901, and Robert Hutchison, an Englishman, in 1907. Both of these syndromes are distinctly characteristic and are readily recognized by the author's names in the literature throughout the world. These papers were short, both referred to the literature, which they carefully compiled to prove their theses, and were illustrated. At the time of publication, both authors were young, Pepper only 27 and Hutchison was 36 years of age.

Testis.—The unusually interesting and complex subject of cancer of the testicle has strangely enough produced only three terms of eponymic character. Louis Charles Malassez (1842-

1910), a French physiologist and pathologist, described characteristic cysts of the testicle, which, at least on the European continent, received wide recognition. Today this condition is rarely found as he described it, and if cysts are present, they are generally recognized as arising in the large group of mixed or teratoid tumors.

In 1906 Maurice Chevassu published his famous Paris thesis on seminoma of the testicle. He reviewed the literature carefully from the time of Monod and Terrillon, from 1888 to 1905, inclusive. His study comprised 90 unpublished cases. His careful detail of the histologic examination in the unicellular tumors has made his description a classic in testis cancer. Chevassu has maintained his interest in these tumors ever since and is not only one of the leading authorities on the subject, but an internationally known urologist as well.

In 1925 Gordon Bell, of England, in the course of a review of collected testis tumor material, which was published in two parts, recognized an unusual tumor arising from the adult tubules. This tumor, present in an older age group than the average, has a distinctive clinical course and justly deserves to be known as "Bell's tumor of the testicle"—at least in the opinion of James Ewing, who has studied these cancers extensively since 1911.

In 1930 Selmar Aschheim, in a study of tumors in women, added a brief note without detail concerning the hormonal study of a male patient with chorionepithelioma of the testicle. This case was added to 9 others by Bernhard Zondek and reported extensively in 1932. This method, known as the Aschheim-Zondek reaction, has added a new biologic approach to these complex tumors in both men and women.

Prostate.—Cancer of the prostate is a disease that has been clearly recognized only since the time of Sir Henry Thompson. It remained for the great master of the Necker Clinic at Paris, the immortal Félix Guyon (1831–1920), to recognize and describe the importance of the frozen pelvis in the male, known as the prostato-pelvic syndrome. Without the aid of roentgen diagnosis, he recognized the seriousness of this condition, based only on clinical examination of his patients, and he reported cases in 1887.

Ovary.—The study of the sex cell tumors involving the ovary roughly parallels that of the testicle. In 1896 Frederick Krukenberg reported 6 cases of metastatic tumors in the ovary in a 35-page article. The author was only 25 years old when he described this tumor, now well known throughout the world.

Julius Jarcho, in 1938, found an interesting case report in the Descriptive Catalogue of the Pathological Specimens contained in the Museum

nucleus and its division, in 1882 added to Virchow's aphorism omnis nucleus e nucleo. These laws are now fundamental to pathology.

Jean Bergonié (1857-1925) and L. Tribondeau (1872-circa. 1914), both of France, enunciated a fundamental law of irradiation of cancer therapy in 1906. This law states in effect that the sensitivity of cells to irradiation varies directly with the reproduction capacity of cells and inversely with their degree of differentiation.

For many years James Ewing has fought for a more precise limitation of the evidence in medicolegal relationship of trauma to cancer. He has listed five essential criteria in the study of such cases, which have now become generally accepted. A summary of his conclusions appeared in May, 1935. He generously gives credit to K. Thiem, in 1915, for an early statement of similar criteria, but full credit for an understanding of the importance of these postulates in medicolegal procedures belongs to Ewing.

# Summary of General Opinions For and Against the Use of Eponyms

Clifford Allbutt suggested a comprehensive nomenclature which fits the disease, and not only identifies it, but also helps to classify it. "A name then must be a seal, not a label." From this point of view eponymic names are ideal because they do not characterize the nature of the disease and their use is based more or less upon convention—in fact they are born very often from embarrassment because they designate a newly discovered but not yet fully recognized syndrome which cannot be designated by an incontestable term.

The custom of designating diseases by proper names (usually those of the discoverers), which the English and Americans prefer to call eponyms, is not very old. Such eponyms were mentioned only sparingly in the medical literature of the eighteenth century, and their use became more common only after the middle of the nineteenth century, reaching the peak at the present time. The reason for this increase is rarely due to the intention to create a permanent monument for the discoverer of the disease. The main reason for their use is doubtless the tendency of our modern age to express ourselves briefly, a tendency which we also find in other branches of human endeavor.

In 1912, Fielding Garrison wrote his only paper on the subject of eponyms and was so definitely set against their use that he never referred to them again, even in the four editions of his history. He comments that the use of adjective expressions derived from the names of persons and places is by no means confined to the medical sciences, but is probably coexistent with the history of

European culture. After a discussion of many of the most common terms in medicine and surgery, he states that it is evident from the examples cited, that no beneficent goddess, but only blind chance, has presided over the devising of eponyms. As His has pointed out, they have little to do with the distribution of historical justice, and the attempt to repair the omission by the use of the hyphen seems a rather clumsy expedient. Garrison concluded that it ought to be the aim of medical teachers and editors to prevent the growth of eponyms from becoming a nuisance or a fad. This could best be done by editorial revision of the titles of medical papers in which undesirable or unnecessary eponyms occur. He suggested that the college instructors might regard the indiscriminate use of eponyms as an evil, which, like all bad habits, could best be discontinued in its early stages, by nipping it in the bud. An improvement would be to give the name of the disease first, and let the bracketed eponym follow it.

Sir Humphrey Rolleston, in an entertaining paper in 1937, listed several advantages of eponyms, the first of which I believe extremely important, in that they may stimulate an interest in medical history; also, that the single name has obvious practical advantages over a cumbrous descriptive title; third, that the hyphenated eponym may suggest, and even contain in a nutshell, the early history of a disease. He mentions some of the drawbacks of eponyms: that they increase the student's not inconsiderable difficulties upon beginning a new subject: second, that the hyphenated eponyms are not always assigned with strict chronologic exactitude. Another drawback of the eponym habit, the outcome of hero worship, is that several diseases may be called after the same famous man, and a still further complication may be that two or more men may find their names attached to different diseases, signs, operations, tests, or injuries. He concludes that it may indeed be difficult, even for the elect, to deliver a correct eponymic judgment.

In the last Index to the Current List of Medical Literature, A. Seidell comments that the practice of designating diseases, operations, signs, etc., by the names of individuals greatly complicates the classification under subject headings. A count in a recent edition of Dorland's Medical Dictionary showed the following approximate numbers of proper names used in this manner: diseases, 565; syndromes, 165; operations, 450; signs, 525; tests, 916; methods, 300; phenomenon, 92; reaction, 150; reagent, 66. Thus in only these selected cases there are more than 3,200 names of individuals which add to the difficulty of searching the accumulated literature of medicine.

Transactions. Since then this has been known as the Bence-Jones test for protein, which produces a reddening of the urine on the addition of nitric acid. Otto Kahler (1849-1893) wrote on albumosuria in 1889 and is quoted in Europe regarding this obscure disease. In 1921 James Ewing of the Memorial Hospital in New York gave an inclusive description of a single case of bone tumor, now known as endothelial myeloma, which was promptly quoted in the world's literature as Ewing's sarcoma. This tumor is so unique that it has retained a separate classification in the Bone Tumor Registry of the American College of Ewing's brevity in confining this report to 8 pages compares with Paget's classic short report and again demonstrates that the master of a subject can state his case in a few concise words.

Gastrointestinal Tract.—It is rather surprising, in reviewing the literature of gastrointestinal cancer, which leads all others in statistical analysis, that very few eponyms are associated with it. The Bard-Pic syndrome describes the slow, painless jaundice and distorted gallbladder, with cachexia and loss of weight, indicating carcinoma of the head of the pancreas. This sign was defined in 1888 by Louis Bard and A. Pic, and is still of great aid in the differential diagnosis of obscure intra-abdominal cancer. Other signs were described by Troisier, Virchow, Strauss, and Blumer. Ludwig J. Courvoisier (1843-1918) described an extremely useful sign indicating the presence of extrahepatic tumors-if a gallbladder is much distended from obstruction of the common duct, tumor is the probable cause instead of calculus. This sign was described in 1890 in an extensive German monograph. 1884 Josef Thomaver (1853-1927) described a sign which distinguishes inflammatory from noninflammatory or malignant ascites; the mesentery shrinks, pulling the intestines in a pocket.

Metastases.—Charles Emile Troisier (1844-1919) in 1886 discussed three cases of metastatic cancer in a 5-page article. His name has since been attached, especially by the French, to enlarged lymph nodes above the clavicle, as a sign of metastatic intra-abdominal cancer. The primary tumor is usually in the stomach, but it may be anywhere in the abdominal cavity. The fame of Rudolph Virchow is also associated with the same phenomenon. However, the exact reference to his description is difficult to find and may have been passed along verbally by Virchow's many pupils. The report is published in Die Medizinische Reform, of 1849, a semipolitical journal, which aired views in sympathy with the revolutionary movement then in progress.

Hermann Strauss (1868- ) has been credited with an eponymic sign describing tumor

metastasis in Douglas' pouch, which projects into the rectum. However, recognition goes to George Blumer, who in 1909, in a 6-page paper in the Albany Medical Annals described what is now generally known as Blumer's rectal shelf, a diagnostic sign of great importance in the recognition of abdominal cancers. He was one of the few authors in this series who years later wrote again on the same sign, more extensively and in the same journal, in 1938.

Nerves.—Theodor Schwann (1810-1882), a German anatomist and physiologist, described the myelin sheath of the medullary nerve fibers. This tissue is so histologically distinctive that the tumors invading it are now known quite generally as schwannoma, although he did not study the neoplasms involving nerves.

In an extensive monograph published in German (1882) Friedrich D. von Recklinghausen (1833–1910) described as an entity multiple soft fibromas of the skin which had arisen from neuromas—hence the term neuromatous fibromas or neurofibromas. Much earlier Rudolph Virchow showed an excellent plate of the condition as a frontispiece in volume one of his famous treatise on tumors. Von Recklinghausen's description first appeared as a part of the Festschrift, in honor of the foundation of the Pathological Institute in Berlin, and was dedicated to Virchow.

#### Microscopic Grading

In 1920 Albert Broders, pathologist of the Mayo Clinic, devised a practical method of grading cancer and reviewed 537 cases of squamous cell carcinoma; 9 of them in detail with 12 illustrations. This paper was the first in which the clinical malignancy of a large series of cases was expressed numerically, with a high degree of accuracy. General observations had been made by early pathologists, especially since the time of von Hansemann in 1890 until 1902 when von Hansemann published his monograph. He popularized the term anaplasia (backward to form). As Broders has pointed out, this great study was considered of academic interest only and failed to be taken seriously by other pathologists. It is to Broders' credit that the application of such an index has been used and discussed since his contribution in 1920.

#### Laws and Postulates

It is rather difficult now to imagine the chaotic state of pathology and bacteriology previous to 1850. Rudolph Virchow (1821–1902), the greatest figure in the history of pathology, stated in 1858 that omnis cellula e cellula, or that a new growth of cells presupposes already existing cells. Later Walther Flemming (1843–1905), after publishing a masterly monograph on the

#### A COUNTY CANCER PROGRAM

J. Louis Neff, F.A.P.H.A., New York City

NASSAU County is a suburban area, situated on Long Island, adjoining the City of New York on the east. It has grown in twenty-five years from what was essentially a rural community of about 125,000 to a present population of nearly half a million, supporting war industries of considerable magnitude. Its county department of health is only five years old and the community has never been able to build hospitals fast enough to keep pace with its rapid population growth.

The work of a local cancer committee in such an area would therefore involve problems which might not be duplicated in other sections of the country. This record of our history for the past fifteen years is not intended, therefore, as an outline of what should be done in other local communities, and we hope that its purpose will not be misunderstood. Many of our problems, however, are basic, and perhaps a description of our efforts, our successes, and our failures might serve as an encouragement to other groups who are struggling with the same disappointments and the same discouragements and perhaps offer an inspiration to go ahead and do a better job in less time than it has taken us.

The Nassau County Cancer Committee was organized in 1928 as a branch of the New York City Cancer Committee, and was incorporated as a separate branch of the American Society for the Control of Cancer in 1937. Of the original nine corporate directors five were physicians, four of them past-presidents of the county medical society. There has always existed the closest possible relationship between the Committee and the

mittee and the Society.

The first activities of the Committee were the typical ones of preparing educational articles for the local newspapers and sending speakers to address meetings of local organizations of men and women. Almost at once we were met with the embarrassing situation of having patients consult physicians because of symptoms which might mean cancer, only to have the doctors advise them to "go home and forget it" or "come back in six months if it doesn't go away." We thereupon determined that it was of no value

to advertise to the public the possibility of cancer cure until more of the medical profession could be gotten into a frame of mind in which they would be willing to meet the patient at least halfway.

With the help of the county medical society we arranged a series of postgraduate lectures to be given by prominent cancer specialists. The extent of the local professional interest in the subject can be measured by the fact that in spite of considerable publicity given these lectures, including personal invitation, the attendance at the four sessions was incredibly small, reaching a low, at the final session, of three doctors and two public health nurses.

We thus learned not only what our first objective must be, but we also learned that this objective was fundamental and that it was not going to be easy to attain. We saw that we must provide or secure for the county the tools for cancer control and that these tools must include not merely the necessary x-ray, radium, and hospital accommodations, but that they also must include an enlightened medical profession which would understand the other tools and be enthusiastic about using them.

Remember that this was fifteen years ago; remember also that much of our present knowledge of the diagnosis and treatment of cancer is not much older than that. So it is not surprising that in 1928 our local doctors had not had much experience in looking for or in treating early cancer. Today the doctors in any community are thinking more about cancer than they were fifteen years ago, but this does not alter the fact that the support and assistance of the local practicing physicians is a basic "first" in any cancer control program.

Accordingly, we determined to reduce our contact with the general public to the minimum of giving authoritative advice when it was asked. We stopped our newspaper articles, we stopped our lectures, and we stopped our generalities about "see your doctor." Instead we began to provide postgraduate educational opportunities for the profession: lectures, exhibits, a cancer article every month in the bulletin of the county medical society. And we began to work toward the day when we should have a group of well-trained specialists who were genuinely interested in cancer control and a group of general

Presented at a preliminary meeting of the Annual Meeting of the American Public Health Association, October 11, 1943
Formerly Executive Secretary, Nassau County Medical Society and Secretary, Nassau County Cancer Committee; by Liccutive Director, American Society for the Control of Cancer.

In spite of these obvious difficulties, it is probable that certain major eponymic terms will survive in the medical literature of the future, and will continue to add biographical and historical interest to the subject.
